A commercially available solid-phase radioimmunoassay (RIA) for antibody to hepatitis B surface antigen (HBsAg) was modified to detect the subtypes of HBsAg (*adw, ayw, adr,* and *ayr*) as well as the subtype-specific anti-HBsAg reactivities (anti-*d*, anti-*y*, and anti-*w*). Because the RIA test is available and standardized, the need for preparing and radiolabeling reagents every 45-60 days is circumvented. The necessary antisera and HBsAg subtypes can be used without purification. High dilutions of the monospecific reagents are used so that only small quantities of the original antisera are needed (each 0.1 ml of antiserum provided 250-8,000 tests). In endpoint dilution studies, RIA subtyping was 10-50 times as sensitive as rheophoresis or counterelectrophoresis (CEP). In tests of sera from chronic HBsAg carriers, 12% of the samples could not be subtyped by CEP or rheophoresis, whereas RIA was capable of detecting the subtype in all samples. Where all three methods were positive, RIA gave results identical to those of rheophoresis and CEP. In studies of type B hepatitis in man and chimpanzees from which weekly bleedings were available, RIA subtyping of HBsAg increased the ability to detect subtypes by 25-30%. Persons exposed to an infectious plasma pool containing HBsAg with both *adw* and *ayw* subtype reactivities were frequently found to circulate HBsAg with both *d* and *y* subdeterminants. Using RIA, 54% (37/68) of these patients demonstrated both *d* and *y* reactivities. The occurrence of both subtypes together (chiefly in patients exposed to both subtypes and rarely in chronic carriers) suggests that the apparent simultaneous *d* and *y* infections were not attributable to false specificity of the reagents. Whether these samples with both *d* and *y* subdeterminants of HBsAg represent the circulation of two populations of HBsAg particles, one *adw* and one *ayw*, as opposed to the circulation of hybrid *adyw* particles, cannot be ascertained by this method, Not all anti-HBsAg-positive samples can be subtyped, even by RIA. Some samples appear to possess anti-*a* but no anti-*d* or anti-*y*. Anti-*w* is found only rarely. Among the anti-HBsAg-positive samples studied, about 75% of the specimens could be subtyped for anti-*d* or anti-*y*, and most samples possessed anti-*a* in excess of either anti-*d* or anti-*y*. Further studies are needed to characterize the onset, persistence, and general incidence of the subdeterminant specificities of anti-HBsAg in relation to anti-*a*.

5084 LIVER DISEASE AND THE IMMUNE RESPONSE TO AUSTRALIA ANTIGEN. (Spa.)

Lissen Otero, E.; Caraballo Guijarro, R.; Crivell Charneco, C.; Andreu Kern, F. (Ciudad Sanitaria "Virgen del Rocio," Sevilla, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(2):213-226; 1976.

Clinical and laboratory observations of healthy carriers of viral hepatitis of patients with acute hepatitis and of patients with chronic hepatopathies are reviewed with respect to their immune responses to hepatitis B viral antigen (HBAg). The carriers usually showed the highest blood and liver tissue levels of HBAg; they usually had normal B and T lymphocyte levels, a substantial predominance of histocompatibility antigens HL-A3 and W19, and a lowered immune response to HBAg. In patients with acute hepatitis B, reduced levels of B and T lymphocytes were accompanied by lymphocytotoxic antibodies and antibodies against HBAg. Nonspecific cellular immunity was lower during the acute episode and returned to normal during convalescence. Sensitization of specific cell immunity was noted in some acute hepatitis patients (indicated by migration inhibiting factor response to HBAg). In chronic aggressive hepatopathy patients, the following tendencies were noted: (1) predominance of histocompatibility antigens HL-A1 and HL-A8, (2) reduced levels of T lymphocytes and increased levels of lymphocytes, (3) reduced nonspecific cell immunity, and (4) specific cell sensitization. One theory suggests that the healthy carriers do not respond immunologically to infection either because of a failure to recognize HBAg as foreign or because of an inability to respond after recognition. The development of an immune response to the viral antigen would precipitate an acute hepatitis episode. Another theory proposes that once the invading virus has triggered first T and then B lymphocytes, aggressive immune hepatocytolysis, a patient can follow one of two courses: (1) circulating antibodies can effectively clear the system of HBAg, in which case T lymphocytes stop being stimulated and the immune process winds down as in acute hepatitis, or (2) circulating antibodies fail to eliminate HBAg, the infection continues to spread, and the process is perpetuated, as in case of chronic aggressive hepatitis. This latter hypothesis best explains the pathogenic mechanism of self-perpetuating chronic hepatitis in patients who are HBAg negative; however, none of the proposed theories provides a completely satisfactory explanation.

5085 EXTRINSIC MODULATION OF HUMAN T-LYMPHOCYTE E ROSETTE FUNCTION ASSOCIATED WITH PROLONGED HEPATOCELLULAR INJURY AFTER VIRAL HEPATITIS. (Eng.)

Chisari, F. V.; Routenberg, J. A.; Fiala, M.; Edgington, T. S. (Scripps Clinic and Res. Foundation). *J. Clin. Invest.* 59(1):134-142; 1977.

The association between the extrinsic defect of T lymphocyte E rosette (ER) function (due to the presence of rosette inhibitory factor in autologous serum) and chronic virus-initiated hepatocellular injury following viral hepatitis was examined. The extrinsic defect was observed in 7/8 patients with longstanding chronic active hepatitis and in all of 10 patients with unresolved hepatitis 12 weeks after the onset of jaundice. In contrast, none of nine patients with resolved hepatitis had extrinsically defective ER function 12 weeks after the onset of jaundice, whereas eight of them displayed an intrinsic defect of ER function at that time. Among the various viral and liver diseases studied, rosette inhibitory factor appeared to be specific for hepatitis A and B viral infections. None of 64 sera from a variety of viral and mycoplasma infections (including Epstein-Barr virus or cytomegalovirus mononucleosis with associated hepatitis) or 15 sera from patients with chronic nonviral liver diseases (Laennec's cirrhosis, hemochromatosis, primary biliary cirrhosis, extrahepatic bile duct obstruction, metastatic liver disease, idiopathic cirrhosis) were positive for rosette inhibitory factor. This factor and its associated extrinsic defect in ER function appear to correlate with a particular type of hepatocellular injury initiated by the hepatitis A and B viruses that may have a propensity for persistence and/or progression to an aggressive form of chronic hepatitis.

5086 A RANDOMIZED, DOUBLE BLIND CONTROLLED TRIAL OF THE EFFICACY OF IMMUNE SERUM GLOBULIN FOR THE PREVENTION OF POST-TRANSFUSION HEPATITIS: A VETERANS ADMINISTRATION COOPERATIVE STUDY.

(Eng.) Seeff, L. B.; Zimmerman, H. J.; Wright, E. C.; Finkelstein, J. D.; Garcia-Pont, P.; Greenlee, H. B.; *et al.* (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Gastroenterology* 72(1):111-121; 1977.

A study was conducted in 11 Veterans Administration hospitals (2,204 patients) during a 49-month period to compare the relative efficacies of immune serum globulin (ISG; 1,094 patients) and an albumin placebo (1,110 patients) for the prevention of post-transfusion hepatitis (PTH). PTH developed in 241 (10.9%) of the patients. The results showed that ISG significantly reduced (p=0.045) the incidence of icteric-type non-B hepatitis only (inferred also to be type non-A hepatitis). Adverse reactions were rare, and the ISG did not appreciably alter the incubation period or duration of the disease. ISG did not have an effect on total incidence of PTH among recipients of commercial donor blood (p<0.015). Type-B hepatitis occurred in less than 20% of the 241 patients studied. The incidence of PTH was higher among white patients (12.0%, p<0.01) than among black patients (7.9%). Type-B hepatitis and infection occurred significantly more often (p<0.005 and p<0.001, resp.) in the hepatitis B surface antibody (anti-HBs)-negative group. The incidence of
total hepatitis was six times greater (p<0.001) i
the recipients of commercial blood (15.5%) than i
recipients of volunteer donor blood (2.6%).
The incidence of total hepatitis rose almost line
ly with the number of units of commercial blood a
ministered, reaching a peak of 40.6% among those
who had received 11 or more units of this form of
blood. Recipients of positive hepatitis-B surfac
antigen (HBsAg-positive) donor blood had a greate
incidence of PTH (p<0.001) than did recipients of
HBsAg-negative blood (27.1% compared to 10.5%).
Elimination of the use of commercial blood and
HBsAg-positive blood was suggested. The importan
of defining the agents responsible for type non-A
non-B hepatitis is stressed.

5087 SILYMARIN FOR THE TREATMENT OF ACUTE VI HEPATITIS? REPORT OF A CONTROLLED TRIA

(Ger.) Bode, J. Ch.; Schmidt, U.; Durr, H. K.
(Medizinische Klinik der Universitat, Mannkopff-
strasse 1, D-3550 Marburg/Lahn, W. Germany). *Med*
Klin. 72(12):513-518; 1977.

The effectiveness of silymarin (3 x 140 mg/day,
p.o.) was studied in 51 patients with acute viral
hepatitis. Thirty-two patients were hepatitis B
surface antigen (HBsAg)-positive. A similar grou
of 100 patients served as controls (61 patients
HBsAg-positive). Laboratory tests (total serum b
lirubin, SGOT, SGPT, and alkaline phosphatase act
ities and prothrombin time) were performed every
5-7 days over a period of 5 weeks beginning with
onset of jaundice. There were no statistically
nificant differences between the treated group a
controls during normalization of the biochemical
parameters. The findings indicate that silymari
has no favorable effect on the course of acute v
hepatitis.

5088 METABOLISM OF HEXOBARBITAL IN PATIENTS WITH ACUTE HEPATITIS AND CIRRHOSIS. (

Richter, E.; Gallenkamp, H.; Keller, B.; Brachte
D.; Zilly, W.; Breimer, D. D. (Medizinischen Uni
ersitatsklinik Wurzburg, Josef-Schneider-Strasse
8700 Wurzburg, W. Germany). *Z. Gastroenterol.* 6
381-388; 1977.

The metabolism of hexobarbital (HB; 7.32 mg/kg b
i.v. infusion in 60 min) was studied in 16 patie
with acute hepatitis, 18 patients with liver cir
rhosis, and in 21 volunteers. Plasma HB was det
mined by gas chromatography, and HB clearance wa
calculated from the plasma-concentration curve
versus time. Additional experiments were perfor
in rats with galactosamine-induced hepatitis. H
clearance was normal in half of the patients wit
acute hepatitis, but it was diminished in the ot
half. However, serum bilirubin level, SGPT, and
factor V activity were similarly pathological in
both groups. The clearance of HB did not correl
with its half-life. The 18 cirrhotic patients
were subdivided into two groups: those with com
pensated cirrhosis and those with the decompensa
form plus ascites and esophageal varices. Nearl

ll the cirrhotics had a diminished HB clearance, specially the latter group. In the volunteers, 0-60% of the administered dose was excreted as eto-HB, compared with 10-20% in the acute hepa- itis patients and only 5% in the cirrhosis patients. ver 90% of HB was eliminated within 24 hr in all hree groups. Rats with galactosamine hepatitis howed diminished HB clearance, which can be attrib- ted to a decreased microsomal cytochrome P450 con- ent and an increase in the half-life of HB.

089 RENAL CLEARANCE OF GLUCURONATE-CONJUGATED BILIRUBIN FRACTIONS IN VARIOUS TYPES OF AUNDICE. III. JAUNDICE RESULTING FROM ACUTE IFFUSE LIVER DISEASE. (Spa.) Candel Monserrate, .; Diaz-Rubio Garcia, M. (Hospital Clinico San arlos, Madrid, Spain). *Rev. Esp. Enferm. Apar. ig.* 46(3):257-270; 1975.

enal clearance of glucuronate-conjugated bilirubin raction was evaluated in nine patients with diffuse cute hepatopathies: spherocytosis and post-trans- usion acute hepatitis (1/9), acute viral hepatitis 7/9), and acute viral hepatitis with Malta Fever 1/9). The following measurements were taken: irect- and indirect-reacting bilirubin in blood and rine; mono- and diconjugated bilirubin in blood and rine; pH, density, albumin level, and volume of rine; creatinine clearance; renal clearance of bili- rubin; blood pH; serum albumin, and gammaglobulins; romine; prothrombin; SGOT, SGPT, and acid and alka- line phosphatases. As in normal subjects and atients with hemolytic jaundice, the monocon- jugated fraction predominates in blood and the iconjugated fraction in urine; renal clearance f the diconjugated fraction was greater than clear- nce of the monoconjugated fraction. Renal clear- nce of both fractions was significantly lower in hese patients than in normal controls ($p<0.01$ for he monoconjugated fraction; $p<0.05$ for the dicon- jugated fraction). Renal clearance of both con- jugated fractions did not differ significantly among hese patients and patients with other types of jaundice (including hemolytic anemia, diffuse chronic hepatopathy, tumor hepatopathy, or obstruc- tive jaundice). Direct-reacting bilirubin predominated over indirect-reacting bilirubin in both blood and urine. A good correlation was also recorded between monoconjugated levels in urine and clearance. As in the controls, no correlation was shown between bilirubinemia and bilirubinuria, and no relationship was discovered between clearance and blood pH.

5090 SMALL VIRUS PARTICLES IN FAECES OF PATIENTS WITH INFECTIOUS HEPATITIS (HEPATITIS A). (Eng.) Skidmore, S. J.; Boxall, E. H. (East Birmingham Hosp., Birmingham B9 5ST, England). *J. Med. Microbiol.* 10(1):43-48; 1977.

Fecal samples from 41 patients with infectious hepatitis and their contacts were investigated for the presence of hepatitis A-associated viral particles. Immune electron microscopy or cesium chloride density-gradient centrifugation revealed viral particles in 16 patients. The latter method was invaluable in detecting small numbers of viral particles. The particles had a buoyant density of 1.34-1.35 and a size range of 21-28 nm. In several samples, tailed phages were identified, but always at a different buoyant density from that of hepatitis-A-associated particles. Cesium chloride density-gradient centrifugation was carried out in six fecal suspensions from which Echovirus type 19 had been isolated. This virus also banded at density 1.34, and its size (25-26 nm) was similar to that of hepatitis A-associated particles. However, hepatitis A-associated particles caused no cytopathic effects in Hep-2 cells, whereas Echovirus recovered from gradients did.

LIVER AND BILIARY TRACT

Chronic Hepatitis

5099 CHRONIC ACTIVE HEPATITIS IN CHILDREN. A CLINICAL AND IMMUNOLOGICAL LONG-TERM STUDY. (Eng.) Lidman, K.; Biberfeld, G.; Sterner, G.; Norberg, R. (Danderyd Hosp., S-18203 Danderyd, Sweden). *Acta Paediatr. Scand.* 66(1):73-79; 1977.

The clinical course, liver function tests, immunoglobulins, autoantibodies, and antibodies to measles and rubella were followed in seven children (aged 9-15 yr) with chronic active hepatitis (CAH) on immunosuppressive therapy. Their course was followed 1-10 yr after the initiation of immunosuppressive therapy. No patient had known contact with viral hepatitis A or B or with hepatotoxic drugs. In five cases, the onset of disease was acute with nausea, fatigue, and jaundice. One patient had measles 1 month before she developed jaundice and the remaining patient had rubella 6 months before the onset of jaundice. All patients had markedly increased IgG (peak levels in each patient, 17.9-51.4 g/1), high titers of smooth muscle antibodies (SMA; highest titers recorded in each patient, 100-800), and antinuclear antibodies of the IgG class in the earliest serum specimens tested. Therapy resulted in an improved sense of well-being and a decrease in SGOT, IgG, and SMA titers. Very high titers of measles antibodies (Morbilli HI titer, 80-12,800; Morbilli HLI titer 640-40,960) were observed in all cases. One patient died of liver failure after 5 yr of illness. The other patients have survived and are able to live a normal life. The possibility of CAH should be considered when children develop symptoms of hepatitis. Long-term immunosuppressive treatment with regular clinical and laboratory evaluation and the estimation of SMA titers are useful in young patients with CAH.

5100 HISTOPATHOLOGICAL FEATURES IN MIXED TYPES OF CHRONIC AGGRESSIVE HEPATITIS AND PRIMARY BILIARY CIRRHOSIS: CORRELATIONS OF LIVER HISTOLOGY WITH MITOCHONDRIAL ANTIBODIES OF DIFFERENT SPECIFICITY. (Eng.) Kloppel, G.; Seifert, G.; Lindner, H.; Dammermann, R.; Sack, H. J.; Berg, P. A. (Pathologisches Institut, Universitat Hamburg, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 373(2):143-160; 197

Studies were carried out to determine whether the liver histopathology of 14 patients with chronic inflammatory liver disease, cholestasis, and mitochondrial antibodies against mitochondrial antigen fractions of 1.19 density (primary biliary cirrhos [PBC] antigen) differs from that of 13 patients with antibodies against fractions of 1.13 density chronic active hepatitis-primary biliary cirrhosis [CAH-PBC] mixed-type antigen). For comparison, th liver biopsies of 17 patients with chronic aggress hepatitis (CAH) and antinuclear and/or antismooth muscle antibodies, but without cholestasis and mit chondrial antibodies, were evaluated. The 14 patients with mitochondrial antibodies against the P antigen showed the typical histological features of PBC. The 13 patients with mitochondrial antibodies against the CAH-PBC mixed-type antigen had heterogenous liver alterations. In 11 cases, high active CAH and/or active postnecrotic cirrhosis (AC) were found, both with augmented ductular proliferation. Some of these cases showed distinct c teria of PBC as early bile duct lesions or absence of regular bile ducts. The liver histology of one case corresponded to classical PBC, another case t chronic persistent hepatitis. The CAH-patients wi out cholestasis and mitochondrial antibodies only occasionally showed bile duct proliferation. A high correlation was found between mitochondrial antibodies against the CAH-PBC mixed type antigen and highly active CAH or early AC with augmented ductular proliferation. This result represents an overlapping of CAH and PBC. In contrast, the case with antibodies reacting to the PBC antigen showed the slowly progressive liver changes of typical PBC.

5101 ANTIBODY TO HEPATITIS B CORE ANTIGEN IN CHRONIC HEPATITIS AND PRIMARY BILIARY

CIRRHOSIS: EVALUATION BY A NEW AUTOLOGOUS SOLID PHASE RADIOIMMUNOASSAY. (Eng.) Grady, G. F.; Kaplan, M. M.; Vyas, G. N. (State Lab. Inst., 305 South St., Boston, MA 02130). *Gastroenterology* 72(4):590-593; 1977.

The antibody to core antigen of hepatitis B virus (anti-HBc), was assayed by a new solid phase sandwich radioimmunoassay inhibition method in the sera of 26 patients with hepatitis B surface antigen (HBsAg)-negative chronic active hepatitis (CAH) and 31 patients with primary biliary cirrhosis (PBC). The sensitivity of the method was validated by finding anti-HBc titers averaging >1:1,000 in a group of chronically HBsAg-positive individuals, four of whom had chronic persistent hepatitis and four of whom had no histological or biochemical evidence of liver disease. However, anti-HBc was not detectable in any of the 26 patients with HBsAg-negative CAH. Sera from 2 of the 31 PBC patients contained anti-HBc but only in low titers, a distribution of anti-HBc similar to that found among a comparison group of 100 normal subjects. Anti-HBc testing among PBC patients and control subjects identified a few persons in whom negative tests for HBsAg and anti-HBs failed to identify previous hepatitis B infections. Nevertheless, the uniformly negative tests for anti-HBc among the HBsAg-negative patients with CAH provide additional evidence that this subgroup, typically young to middle-aged women, seldom derive CAH from hepatitis B infection.

5102 AUTOANTIBODIES, IMMUNOGLOBULINS AND HEPATITIS B ANTIGEN IN CHILDREN WITH CHRONIC LIVER DISEASE. (Eng.) Dubois, R. S. (Royal Alexandra Hosp. Children, Bridge Rd., Camperdown, N.S.W. 2050, Australia). *Aust. Paediatr. J.* 12(3):163-166; 1976.

Smooth muscle antibody, mitochondrial antibody, serum immunoglobulin G levels, and hepatitis B antigen (HBAg) were measured in the sera of 20 children with extrahepatic biliary atresia, 8 with intrahepatic biliary atresia, and 6 with posthepatic (neonatal) cirrhosis. Smooth muscle antibody was not found in any patient with posthepatic cirrhosis, but it was present at dilutions up to 1/40 in four patients with extrahepatic atresia and four patients with intrahepatic atresia. Only four patients with extrahepatic biliary atresia had normal IgM levels, whereas these levels were uniformly normal in the other two groups. Serum IgA was normal in six patients with intrahepatic atresia, but in only two with posthepatic cirrhosis, and in none of the patients with extrahepatic biliary atresia. Serum IgG levels were elevated in 10 patients with extrahepatic biliary atresia, 4 with posthepatic cirrhosis, but in only 1 with intrahepatic biliary atresia. HBAg was absent in the sera of three groups. No patient had mitochon--drial antibody. The absence of HBAg in the patient's sera suggests that persistent hepatitis B antigenemia is not responsible for the perpetuation of the cirrhotic process in biliary atresia or neonatal hepatitis.

5103 SERUM ANTIBODIES AGAINST LIVER AND KIDNEY MICROSOMES. CHARACTERISTICS OF A SUBTYPE OF CHRONIC HEPATITIS. (Spa.) Katz, S.; Radici, J. V.; Roquel, L. (Hospital Escuela Jose de San Martin, Faculdad de Farmacia y Bioquimica, Buenos Aires, Argentina). *Arq. Gastroenterol.* 13(1):13-17; 1976.

Serum antibodies against liver and kidney microsomes were discovered in five patients with various hepatopathies. In four of five patients, the onset of illness occurred before 10 yr of age. The patients are described briefly: a 12-yr-old girl with chronic hepatitis, recurring severe jaundice, and hypertransaminasemia; a 26-month-old girl with highly developed chronic hepatopathy, jaundice, elevated transaminases, and probable developing cirrhosis; a 9-yr-old boy with a fatal case of severe cirrhosis with ascites, splenomegaly, portal hypertension, jaundice, and very high transaminase levels; a 19-yr-old boy with chronic hepatopathy in remission, treated successfully with corticosteroids; and a 26-yr-old woman with recurring prolonged episodes of jaundice. The microsomal antibodies occurred in only 0.14% of 3,560 subjects tested. The authors suggest that the presence of these antibodies is a characteristic of a particular type of chronic hepatopathy, and that systematic examination for the antibodies in cases of infantile jaundice or prolonged or recurring hepatopathies would allow more frequent diagnosis of the pathology.

5104 COMPLEMENT FIXING HEPATITIS B CORE ANTIGEN IMMUNE COMPLEXES IN THE LIVER OF PATIENTS WITH HBs ANTIGEN POSITIVE CHRONIC DISEASE. (Eng.) Rizzetto, M.; Bonino, F.; Crivelli, O.; Canese, M. G.; Verme, G. (Dept. Gastroenterology, Ospedale Mauriziano Umberto I, Turin, Italy). *Gut* 17(11):837-843; 1976.

Immunofluorescence studies were made of 152 biopsies from patients with hepatitis to detect the presence of hepatitis B virus surface antigen (HBsAg) and core antigen (HBcAg), IgG, and human complement-fixing activity. Seventy-two patients had HBsAg in their serum. Strong nuclear and occasionally weak cytoplasmic complement binding was observed in all of the HBcAg-positive biopsies, except in three which were still in the incubation phase of infectious hepatitis. Complement-binding activity or IgG deposits were not seen in HBsAg-negative biopsies, in biopsies positive only for HBsAg in acute self-limited type B hepatitis, or in serologically positive patients with apparently healthy livers or with only minor lesions. The degree of complement binding and HBcAg fluorescence seemed to depend upon the disease activity. The results of this study suggest that the individual immune response is a key determinant in the progression of HBsAg-positive disease and the nature of its development.

5105 TREATMENT OF CHRONIC INFANTILE HEPATITIS WITH D-PENICILLAMINE. (Ger.) Weingartner, L.; Metzke, H.; Rath, F. W.; Baum, W. F.;

Preiss, U.; Heinrichs, I. (Universitats-Kinderklinik, Leninallee 18, DDR-402 Halle, E. Germany). *Klin. Paediatr.* 189(3):211-219; 1977.

Therapeutic results obtained with D-penicillamine (DPA) in 18 children with liver diseases are presented. Seven patients had chronic active hepatitis, 6 chronic persistent hepatitis, 2 subacute hepatitis, and 3 had liver fibrosis, which was developing into cirrhosis in 1. The duration of the diseases prior to therapy was 7 months to 9 yr. The doses of DPA ranged from 15 to 35 mg/kg. Therapy was usually initiated with a daily dose of 100 mg, that was increased by 100-150 mg weekly to a maximum of 1,000 mg/day. The results of the treatment, which lasted from 5 months to 2 yr, were checked by laboratory tests and liver biopsy. Among the children with chronic active hepatitis, cure was achieved in four, good improvement in one, slight improvement in one, and no response in one, Good improvement was achieved in three of six patients with chronic persistent hepatitis, slight improvement in two, and no response in one. One patient with subacute hepatitis was cured, and very good improvement was achieved in the other. The patient with liver fibrosis developing into cirrhosis did not respond, but very good to good improvement was achieved in two others. Two patients were Australia antigen-positive, neither of whom responded to the therapy. Side-effects (proteinuria after 8 months of treatment and gastrointestinal disturbances) were seen in two patients. The findings indicate that Australia antigen-negative, chronic active hepatitis responds particularly well to DPA therapy.

5106 "NONALCOHOLIC" CHRONIC HEPATITIS IN THE ALCOHOLIC. (Eng.) Goldberg, S. J.; Mendenhall, C. L.; Connell, A. M.; Chedid, A. (Univ. Cincinnati Medical Center, Cincinnati, OH 45267). *Gastroenterology* 72(4):598-604; 1977.

The etiology of biopsy-proven chronic active or chronic persistent hepatitis observed in 10 alcoholic patients was studied. In each patient, the responsible etiological agent appeared to be ethanol. Laboratory abnormalities were distinguished statistically from 121 patients with alcoholic hepatiti
their higher SGPT (262 ± 139 versus 62 ± 7 U/ml,
0.001), lower ratio of SGOT:SGPT (1.96 ± 0.34 ver
4.71 ± 0.40, $p<0.001$), and lower WBC (5,833 ± 763
versus 10,370 ± 742/mm^3, $p<0.01$). However, the o
lap between the groups was sufficiently large tha
without histological confirmation the correct diag
nosis was doubtful for any given patient.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

5109 POSSIBLE RELATIONSHIP BETWEEN THE RATE OF ETHANOL METABOLISM AND THE SEVERITY OF HEPATIC DAMAGE IN CHRONIC ALCOHOLICS. (Eng.) Ugarte, G.; Iturriaga, H.; Pereda, T. (Casilla 15138, Santiago 11, Chile). *Am. J. Dig. Dis.* 22(5):406-410; 1977.

The rate of ethanol metabolism (EMR) was determined in 10 controls; 15 alcoholics with a normal liver; 17 alcoholics with steatosis; 10 alcoholics with necrosis, severe steatosis, and fibrosis; 4 alcoholics with mild fibrosis; 5 alcoholics with cir-
rhosis with necrosis; and 6 alcoholics with cirrho
sis with liver failure and ascites. The patients
were studied after 9-25 days of abstinence (mean,
15 days). A significant increase in EMR ($p<0.01$)
was found in the alcoholics with hepatic necrosis
(265 ± 20.5 mg/kg/hr) compared to alcoholics with
normal liver histology (154 ± 17 mg/kg/hr) and no
alcoholic controls (159 ± 15 mg/kg/hr). In alcoholics with steatosis but without necrosis, a
lesser increase in EMR (207 ± 20 mg/kg/hr, $p<0.05$

as also observed. Patients with only slight fi- rosis without other abnormalities and cirrhotics ith overt liver failure showed EMR similar to con- rols. This study indicates that the increased ate of ethanol metabolism observed in chronic lcoholics may persist much longer than has been reviously described. The data suggest the neces- ity of performing a longitudinal study correlating he amount of alcohol intake, hepatic histology, nd rates and pathways of ethanol metabolism in lcoholic subjects.

110 AMYLASE, HEPATIC ENZYMES AND BILIRUBIN IN SERUM OF CHRONIC ALCOHOLICS. (Eng.) Skude, .; Wadstein, J. (Malmo General Hosp., Malmo, Sweden). *cta. Med. Scand.* 201(1/2):53-58; 1977.

he concentrations of bilirubin and the activities f aspartate aminotransferase (ASAT, GOT), alanine minotransferase (ALAT, GPT), γ-glutamyltransferase GT), total amylase, and pancreatic isoamylase were etermined in the sera of 182 chronic alcoholic men. Twelve percent of the patients had abnormally igh levels of bilirubin (in comparison with a ref- erence group of 97 male controls), 73% had increased SAT, 53% increased ALAT, and 69% increased GT. The ighest values were found after 5-20 yr of well-documented alcoholism. There were 14 alcoholics ith normal enzyme activities, and all had a history f alcoholism of over 20 yr duration. For all par- ameters, the scatter around the mean was greater in he patients than in the controls. In all alcohol- ics, the mean values of ASAT and ALAT activities ere significantly increased ($p<0.001$) in compar- ison with controls. The 48 patients who had had ttacks of delirium tremens showed slightly higher SAT and ALAT activities than did other alcoholics. he mean pancreatic isoamylase level in the serum was decreased in the groups with long-standing alcoholism when compared with the reference group. he frequency of subnormal serum pancreatic amylase was 2% in the reference group, 12% in patients with a 1- to 5-yr history of alcoholism, 19% in patients with a 5- to 10-yr history, 23% in patients with a 10- to 20-yr history, and 26% in patients with a greater than 20-yr history. The combination of ASAT and GT determination was the most sensitive assay in detecting hepatic or extrahepatic ethanol damage.

5111 SERUM LIPIDS IN ALCOHOLIC PATIENTS WITH AND WITHOUT CIRRHOSIS OF THE LIVER, WITH PARTICULAR REFERENCE TO ENDOGENOUS FAMILIAL HYPERTRIGLYCERIDEMIA. (Eng.) Patek, A. J.; Earampamoorthy, S. (Veterans Admin. Hosp., 150 South Huntington Ave., Boston, MA 02130). *Am. J. Clin. Nutr.* 29(10):1122-1126; 1976.

The frequency of hypertriglyceridemia in 40 cirrhotic and 40 noncirrhotic alcoholic patients was investigated. Normal fasting triglycerides (90.6 ± 37.8 and 100.1 ± 36.8 mg/100 ml), total serum cholesterol (179.8 ± 56.5 and 186.9 ± 43.0 mg/100 ml) and fasting blood glucose (102.7 ± 27.8 and 100.5 ± 20.3 mg/100 ml) were found in cirrhotic and noncirrhotic patients, resp.; however, a marked difference in hepatic function tests, e.g., bilirubin (3.2 ± 3.9 and 0.5 ± 0.2 mg/100 ml, $p<0.01$), albumin (2.6 ± 0.8 and 4.1 ± 0.6 g/100 ml, $p<0.01$), alkaline phosphatase (146.9 ± 64.0 and 74.8 ± 30.2 U, $p<0.01$), and SGOT (87.7 ± 62.9 and 32.6 ± 18.6 U, $p<0.01$) were seen in the two types of patients. There was very little evidence of hepatic disease in noncirrhotic alcoholic patients. It is suggested that the frequency of cirrhosis in the general population was not materially affected by subjects with endogenous familial hypertriglyceridemia (type IV hyperlipoproteinemia) even though they showed an exaggerated lipidemic response to ingestion of alcohol. However, these patients might be predisposed to hepatic cirrhosis.

5112 THIAMINE, RIBOFLAVIN, AND PYRIDOXINE SUPPLY IN CHRONIC ALCOHOLISM. (Ger.) Hell, D.; Six, P. (Psychiatrische Universitats-Poliklinik, Petersgraben 1, CH-4004 Basel, Switzerland). *Dtsch. Med. Wochenschr.* 102(26):962-966; 1977.

The thiamine (vitamin B_1), riboflavin (vitamin B_2), and pyridoxine (vitamin B_6) supply was studied in 50 chronic alcoholics and compared with the data for 1,152 healthy controls. Thiamine was determined by the transketolase activation test, riboflavin by the glutathione reductase activation test, and pyridoxine by the glutamic-oxalacetic transaminase test on RBC. The alcoholics had a reduced thiamine and riboflavin supply compared with the controls. A high risk of thiamine deficiency was found in 47.1% of the alcoholics; 13.9% had a risk of riboflavin deficiency. There appeared to be no correlation between thiamine and riboflavin supply. However, there was a significant positive correlation between thiamine supply and hemoglobin (Hb) or diastolic pressure, and significant negative correlations between thiamine supply and bilirubin or γ-globulins and between riboflavin supply and Hb. In the control group, the risks of thiamine and riboflavin deficiency were 2% and 0.4%, resp. The findings indicate that anemia is associated with a reduced thiamine or riboflavin supply. The enzymatic determination of pyridoxine seemed to be influenced by alcohol or by its metabolic processes; therefore, it is not a suitable determinant in chronic alcoholism.

5113 CARCINOEMBRYONIC ANTIGEN, ALCOHOL, AND CIRRHOSIS. (Fre.) Massart, J. P.; Meriadec, B.; Klepping, C.; Martin, F. (Service de Gastro-Enterologie, Faculte de Medecine, blvd. Jeanne d'Arc, 21000 Dijon, France). *Bull. Cancer (Paris)* 63(4):639-648; 1976.

Carcinoembryonic antigen (CEA) levels were measured in the sera of 43 patients with acute alcoholism and in 84 patients with chronic alcoholism (CA) plus cirrhosis of the liver. Liver function tests were also conducted, and α-fetoprotein levels were measured in 69 sera. Histological examination by laparoscopy revealed cirrhosis in 45/84 CA patients;

this finding was also confirmed in 10 others by clinical and biological tests. The CEA level exceeded the normal value of 10 ng/ml in 43/84 CA patients, reaching a maximum of 50 ng/ml. No statistical significance was noted between clinically latent and decompensated cirrhosis. The mean CEA level did not differ with respect to hepatocellular insufficiency. However, the CEA level increased when albumin levels dropped, and it was more elevated in patients with cirrhosis plus biliary retention. No correlation was found between CEA, α-fetoprotein, and other biological tests in the CA patients. Of the 43 acute alcoholism patients, 36% had a CEA level >10 ng/ml. The difference between the two groups is statistically significant.

5114 DUPUYTREN'S CONTRACTURE AND CHRONIC ALCOHOLISM. SEARCH FOR PATHOGENIC RELATIONSHIP WITH HL-A GROUPS. (Fre.) Aron, E. (Clinique medicale A, Centre Hospitalier Bretonneau, 2, bd Tonnelle, 37000 Tours, France). *Sem. Hop. Paris* 53(2):139; 1977.

The pathogenic relationship of Dupuytren's contracture (DC) and chronic alcoholism (CA) with histocompatibility (HL-A) antigens is reviewed briefly. There is a higher incidence of Dupuytren's contraction and chronic alcoholism in Caucasian men, usually developing after 50 yr of age. Stellar angiomas, palmar erythrosis, and DC are signs of CA. Of 116 patients with cirrhosis of alcoholic origin, stellar angiomas were observed in 73%, palmar erythrosis in 47%, and DC in 35% of the cases. The coexistence of all three lesions in 13% of the group attests to the seriousness of the hepatic disease. The occurrence of HL-A was similar in the patients and in controls. Apparently there is no genetic predisposition to DC or CA. Treatment of DC by the cytostatic drug, methyl hydrazine, and complete abstention from alcohol have been proposed.

LIVER AND BILIARY TRACT

Cirrhosis

5118 SEQUENTIAL HEPATOSPLENIC SCINTIGRAPHY FOR MEASUREMENT OF HEPATIC BLOOD FLOW. (Ger.) Biersack, H. J.; Thelen, M.; Schulz, D.; Knopp, R.; Dahlem, R.; Schmidt, R.; Winkler, C. (Institut fur klinische und experimentelle Nuklearmedizin, 5300 Bonn-Venusberg, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 126(1):47-52; 1977.

Hepatic blood flow was measured in 21 patients with liver cirrhosis and portal hypertension and in 10 healthy subjects with a normal liver by sequential hepatosplenic scintigraphy using i.v. ^{99m}Tc-pertechnetate. Pictures were taken by a gamma camera at a rate of 1/sec for 60 sec. The proportion of port
flow averaged 71.1 ± 1.8% in the healthy subjects
versus 20.6 ± 1.5% in the patients. The findings
indicate the considerable value of scintigraphy i
the preoperative diagnosis and postoperative foll
up of portal hypertension.

5119 COMPARISON OF LACTULOSE AND NEOMYCIN I
THE TREATMENT OF CHRONIC PORTAL-SYSTEM
ENCEPHALOPATHY: A DOUBLE BLIND CONTROLLED TRIAL.
(Eng.) Conn, H. O.; Leevy, C. M.; Vlahcevic, Z.

Rodgers, J. B.; Maddrey, W. C.; Seeff, L.; Levy, L. L. (Veterans Admin. Hosp., West Spring St., West Haven, CT 06516). *Gastroenterology* 72(4):573-583; 1977.

A randomized double-blind clinical comparison of neomycin and lactulose was carried out in 33 cirrhotic patients with chronic portasystemic encephalopathy. Sorbitol syrup was used as a control solution along with neomycin and was compared with lactulose syrup and placebo tablets in a double drug protocol. Twenty-nine patients were studied in a crossover investigation in which each received both therapeutic regimens preceded and followed by control periods. Four additional patients received one or the other agent, but did not receive both. Serial, semiquantitative assessments were made in all patients of mental status, asterixis, the trailmaking test (TMT), electroencephalograms (EEG), and arterial ammonia levels. Both neomycin-sorbitol and lactulose were effective in the majority of patients (83 and 90%, resp.). Each of these parameters--mental state, asterixis, TMT, EEG, and NH--was improved significantly by neomycin-sorbitol and lactulose. The post-treatment levels for each of these measures were similar in the neomycin and lactulose-treated groups. Mean stool pH was reduced by neomycin/sorbitol to 6.1 and by lactulose to 5.5 ($p<0.001$). Bowel activity was similar in the two groups. Both drugs were free of toxicity. These investigations demonstrate that both lactulose and neomycin-sorbitol are effective in the treatment of chronic portasystemic encephalopathy.

5120 IMMUNOGLOBULINS AND LIVER CIRRHOSIS: PERSONAL EXPERIENCE.

(Spa.) Cuartero, A. R.; Carril, J. N.; Mora Lara, R. J. (Departamento de Medicina Interna, Catedra de Patologia Medica, Universidad de Granada, Granada, Spain). *Med. Clin.* 65(5):230-233; 1975.

Serum levels of IgG, IgA, and IgM increase in patients with hepatic cirrhosis. Levels were measured in 17 healthy subjects and in 43 patients with hepatic cirrhosis of one of the following types: nutritional alcoholic (20), cryptogenic (14), and posthepatitis (9). No significant differences were noted between Ig levels of patients with different types of cirrhosis, but the patients generally had higher Ig levels than did normal subjects. In 32/43 cases, the levels of IgA, IgG, and IgM were higher; in 6/43 cases IgG and IgA were higher, and in 4 cases IgG and IgM were higher than levels in normal subjects. Several theories are advanced to explain the mechanism of hypergammaglobulinemia in cirrhosis, including hyperfunction of the reticuloendothelial system, reciprocal regulation of plasma proteins and liver, alterations of synthesis and metabolism of immunoglobulins, and plasmocytosis.

5121 EFFECT OF ARGININE KETOGLUTARATE ON THE DETOXIFYING CAPACITY OF THE CIRRHOTIC LIVER.

(Ger.) Muting, D.; Horbach, L. (HEINZ-KALK-Klinik fur Innere Medizin-Gastroenterologie, am Gradierbau, D-8730 Bad Kissingen, W. Germany). *Munch. Med. Wochenschr.* 119(16):535-538; 1977.

The effect of arginine ketoglutarate (3 x 3 g/day, p.o.) on the detoxifying capacity of the liver was studied in 25 patients with liver cirrhosis by determining plasma ammonia and free phenol levels. The patients were on a high-protein diet. They included 10 patients without portal hypertension and 15 with portal hypertension. Compared with the levels measured on the day before treatment, arginine ketoglutarate caused a significant reduction in plasma ammonia and free phenols. The reduced ammonia level was due to a significant enhancement of urea synthesis, measured by the urea nitrogen content in the 24-hr urine. The simultaneous lowering of the free phenol levels can be explained by an improved oxidative decomposition of these substances. Arginine ketoglutarate caused no marked stimulation of insulin secretion.

5122 RENIN LEVELS WITH AND WITHOUT STIMULATION IN LIVER CIRRHOSIS. RELATIONSHIP WITH THE EFFECTIVE RENAL PLASMA FLOW.

(Spa.) Lissen Otero, E.; Gonzalez, M.; de la Rasilla, G.; de Pesquera, F. G.; Fernandez Andrade, C.; Crespo Diez A.; Andreu Kern, F. (Ciudad Sanitaria "Virgen del Rocio," (BR, after 12 hr rest), renin after stimulation *Dig.* 47(6):795-798; 1976.

Plasma renin levels and effective plasma renal flow (EPRF) were evaluated in 31 patients with hepatic cirrhosis after they were maintained for 1 week without drugs on a low-sodium diet (40-50 mEq/day). The following parameters were measured creatinine, urea, creatinine clearance, basal renn (BR: after 12 hr rest) and renin after stimulatio (SR, following 2 hr exercise), EPRF, salt tolerance, and water tolerance. Results were compared to those of 19 normal subjects. In 9/31 patients, renal function was entirely normal in all parameters (roup I); 11/31 patients (group II) had a normal EPRF (<450 cm^3/min); and 10/31 patients (group III) hd an EPRF lower than normal (<450 cm^3/min). The remaining 1/31 is not discussed. In all cases presented, stimulation increased plasma renin leves considerably. In groups I & II, SR values were significantly higher in cirrhosis patients than in normal subjects (3.11 ± 2.16, 2.80 ± 1.67, 1.50 ± 0.51, resp., $p<0.005$; no units were given for SR and BR values). In group III, both BR and R values were significantly higher in patients than in normal subjects (11.76 ± 7.40 and 1.50 ± 0.51, resp.; $p<0.0005$). A strong correlation was noted, therefore, between renin levels and EPRF, the highest plasma renin levels occurring in those patients with the lowest EPRF.

5123 COMPARATIVE STUDY OF URINARY EXCRETION RATES OF PARA-HYDROXY-MANDELIC ACID, HOMOVANILLIC ACID, VANYLMANDELIC ACID IN CIRRHOTIC PATIENTS WITH AND WITHOUT ENCEPHALOPATHY.

Eng.) Zoghbi, F.; Emerit, J.; Fermanian, J.; Bousquet, O.; Legrand, J. C.; Sarrazin, A.; Desgrez, P. (Pitie-Salpetriere, 91 Boulevard de l'Hopital, 75634 Paris

Cedex 13, France). *Biomedicine* [*Express*] 27(1): 37-40; 1977.

To test the hypothesis that false neurotransmitters accumulate in hepatic encephalopathy, the urinary excretion of octopamine, dopamine, and noradrenalin catabolic products (parahydroxymandelic acid, PHMA; homovanillic acid, HVA; and vanylmandelic acid, VMA) were determined in 27 cirrhotic patients with (11) and without (16) portasystemic encephalopathy (PSE). The mean PHMA, HVA, and VMA levels were significantly higher in the patients with PSE (5.12 ± 1.79, 6.75 ± 3.58, and 2.83 ± 1.59 mg/24 hr, resp.) than in the patients without PSE (2.40 ± 1.08 mg/24 hr, $p<0.001$; 3.88 ± 2.73 mg/24 hr, $p<0.02$; and 1.88 ± 0.89 mg/24 hr, $p<0.06$, resp.). There was a significant correlation between PHMA and HVA levels ($r=0.721$, $p<0.02$) and between PHMA and VMA levels ($r=0.079$, $p<0.01$). The higher excretion of PHMA in the patients with PSE suggests increased octopamine metabolism. The increased HVA and VMA excretion, as well as the positive correlations between PHMA and HVA and PHMA and VMA, could be explained by a depletion in stored dopamine and noradrenalin. These observations support the hypothesis that octopamine acts as a false neurotransmitter, and the resulting depletion of dopamine and noradrenalin could explain the neuropsychic phenomena of PSE.

5124 PLASMA PROLACTIN AND PROLACTIN RELEASE IN LIVER CIRRHOSIS.

(Eng.) Wernze, H.; Schmitz, E. (Medizinische Universitatsklinik, Josef-Schneider-Str. 2, 8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol.* 24(2):97-101; 1977.

Plasma prolactin levels were determined by radioimmunoassay in 75 patients with cirrhosis, 27 controls with nonhepatic diseases, and 23 healthy controls. The mean basal prolactin level in the cirrhotic patients (8.5 ± 4.5 ng/ml) was significantly higher than that in controls (5.5 ± 1.7 ng/l, $p<0.001$). The extent and incidence of hyperprolactinemia were more pronounced in the 48 patients with alcoholic cirrhosis than in the 27 patients with nonalcoholic cirrhosis (9.7 ± 4.8 versus 5.7 ± 2.1 ng/ml, $p<0.005$). There was no correlation between the prolactin level and ascites formation or the development of gynecomastia. The prolactin response to thyrotropin releasing hormone (400 μg, i.v.) in all cirrhotic patients was 6.6-fold higher than the basal prolactin level, whereas that of the controls was only 3.9-fold higher. The prolactin response of the alcoholic patients was significantly higher than that of the nonalcoholic patients. It is possible that hyperprolactinemia and increased pituitary hormone reserve reflects hyperestrogenism, but changes of the hypothalamic regulation cannot be excluded.

5125 THE KIDNEY IN CIRRHOSIS.

(Eng.) Wilkinson, S. P. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5 8RX, England). *Tijdschr. Gastroenterol.* 19(3):155-169; 1976.

Different mechanisms leading to sodium and water retention in cirrhosis, the development of renal failure, and the role of the kidney in the production of ascites are reviewed. Abnormalities of renal function are almost invariable in cirrhosis at some stage. These include hemodynamic alterations, renal failure, abnormal electrolyte handling, renal tubular acidosis, glomerular lesions, diabetic nephropathy, interstitial nephritis, and bacterial pyelonephritis. The "overflow theory" of the relation between renal function and ascites formation is based on the hypothesis that the primary abnormality is renal sodium and water retention; this is localized to the peritoneal compartment if portal pressure and plasma oncotic pressure are sufficiently altered to favor fluid transudation. Mechanisms of sodium retention involve two factors: aldosterone and, in the late stages of disease, reduced renal perfusion. Although water is retained secondary to sodium to restore osmotic equilibrium when ascites is forming, the degree of water retention may be greater than the degree of sodium retention and may result in dilutional hyponatremia. Factors involved in water retention include high circulating antidiuretic hormone, increased proximal sodium resorption, the glomerular filtration rate, the amount of solute excreted, and the intrarenal distribution of plasma flow. Renal failure occurs in up to 84% of patients dying of cirrhosis. The nature of renal failure, clinical picture, mechanisms, observations from renal and hepatic transplantation, treatment, and causes of renal failure are discussed. This entity is associated with an intense reversible constriction of the renal vasculature.

5126 OCULAR FUNCTION IN CIRRHOSIS OF THE LIVER.

(Eng.) Krogh, E.; Ring-Larsen, H. (Fuglegardsvaenget 1, 2820 Gentofte, Denmark). *Acta Ophthalmol. (Kbh.)* 55(1):103-110; 1977.

Ophthalmological parameters were investigated in 28 nonalcoholic women with liver cirrhosis. Of the 20 patients who underwent a complete color vision test (Ishihara pseudoisochromatic plates, the Nagel anomaloscope, the Farnsworth 28-hue test, and the Farnsworth 100-hue test), 3 demonstrated acquired color vision defects; 2 patients had increased serum bilirubin levels. Visual acuity, visual field, intraocular pressure, binocular function, slit lamp microscopy, ophthalmoscopy, and tear production were normal in all cases. The results suggest that the frequency of color vision defects is increased in nonalcoholic cirrhotic patients and that alcohol abuse is not a prerequisite for color vision defects in cirrhotic patients.

5127 INFECTED ASCITES IN LIVER CIRRHOSIS. REPORT OF 15 CASES.

(Spa.) Sendra Salillas, S. J.; Gomez Saez, J. M.; Aranda Torres, A. (Ciudad Sanitaria "Francisco Franco," Barcelona, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(6):751-758; 1976.

Bacterial infection of ascitic fluid is an extremely serious complication of hepatic cirrhosis; the clinical courses of 15 patients who developed infections are described. In all patients, death occurred within 11 days of the onset of symptoms. Symptoms were ascites (15), abdominal pain (12), fever (11), shock (10), hepatic precoma (7), jaundice (6), digestive hemorrhage (5), and signs of peritonitis (4). The following bacteria were isolated in the frequencies indicated: *Escherichia coli* (9), *Klebsiella* (2), *Staphylococcus* (1), *Diplococcus pneumoniae* (1), and a combination of *E. coli* and *Streptococcus* (1). All patients were treated with parenterally administered full-spectrum antibiotics, with additional anti-shock therapy, transfusions, and massive doses of corticosteroids or vasoconstrictors when necessary. The three patients who survived the longest (11 days) received more aggressive treatment, including laparatomy, drainage of ascitic fluid, local antibiotics, and related peritoneal lavage. Their deaths were attributed to hepatic insufficiency. Possible sources of the infection are urinary infection, previous sepsis, digestive tube via a change in intestinal flora, and failure of the bacterial filtration activity of the reticuloendothelial system of the liver. A second theory proposes contamination via transmural migration or exogenous contamination (e.g., from laparotomy or paracentesis). The only possibility of effective treatment seems to be early detection by paracentesis and bacteriological examination of the peritoneal exudate, followed by early general and local treatment.

5128 HYPERGASTRINEMIA IN CIRRHOSIS OF LIVER.

(Eng.) Lam, S. K. (Queen Mary Hosp., Hong Kong). *Gut* 17(9):700-708; 1976.

The relationship of acid and gastrin release was examined in 40 cirrhotic patients, and an attempt was made to correlate the findings with the severity of disturbance of liver function and the morphology of the gastric mucosa. In addition, the effect of a portasystemic shunting operation on acid and gastrin release was also studied. The mean basal acid output (BAO) and post-pentagastrin acid output (MAO) of the cirrhotic patients (0.9 ± 0.3 mmol/hr and 6.7 ± 1.2 mmol/hr, resp.) were significantly lower than those in 20 normal controls (2.3 ± 0.3 mmol/hr and 13.6 ± 1.1 mmol/hr, resp.). The mean fasting gastrin level in the cirrhotic patients (41.6 ± 3.1 pmol/l) was significantly higher than that of controls (26.3 ± 3.4 pmol/l), and the postprandial gastrin response was significantly increased and prolonged in the cirrhotic patients. The MAO and integrated gastrin response of the cirrhotic patients did not correlate with the degree of liver function impairment. In five cirrhotic patients, fasting and postprandial gastrin levels remained unchanged after splenorenal shunt operation. A more consistent abnormality of the gastric mucosa as assessed by endoscopy and biopsies appeared to be mucosal congestion with occasional atrophic gastritis. The severity of mucosal abnormality, however, was unrelated to the degree of hypoacidity. The results indicate that the hypergastrinemia in cirrhotic patients is a reflection of gastric hypoacidity and bears no direct relationship to hepatic dysfunction; in addition, the gastric hypoacidity does not accrue solely from mucosal abnormality. This hypoacidity may result from the presence of excessive amounts of circulating acid-inhibiting intestinal peptides, which the diseased liver fails to metabolize.

5129 ANGIOGRAPHY IN THE INVESTIGATION OF PRE-OPERATIVE PORTAL HYPERTENSION. (Fre.)

Dagnelie, J.; Bollaert, A.; Lambilliotte, J. P. (Services de Radiologie, Hopital Universitaire Saint-Pierre, Brussels, Belgium). *J. Belge Radiol.* 59(1):51-70; 1976.

Various angiographic techniques for the diagnosis of portal hypertension (PH) secondary to cirrhosis, including splenoportography (SP), umbilicoportography (UM), ileoportography (IL), hepatic angiography (HA), and subhepatic phlebography (SB), are compared. Direct SP reveals very precise information on the reflux of splanchnic blood in the venous plexus between the splanchnic and cava veins. However, SP does not reveal thrombosis of the portal vein, which occurs in 10% of cirrhotic patients, and the procedure is not indicated in cases of ascites. UM gives good to excellent results in the detection of cirrhosis and hepatic metastases. Together with retrograde catheterization, UM yields precise information on the splenoportal venous axis and venous plexus originating from the portal flux, and it gives immediate results on the permeability of the portal vein. It may be used in splenectomized patients and in cases of ascites or hemorrhagic diathesis. However, an 8%-20% failure rate has been reported with UM. IL yields information about the portal phlebogram and the sinusoidal phase, as well as the derivative venous networks and intrahepatic portal flow. However, it does not give clear data concerning the existence of organic or functional thrombosis of the portal vein. Indirect SP by selective arteriography yields the same information as IL plus detailes of the hepatic arteriogram. HA provides the best results for demonstrating postcirrhotic hepatoma. Manometry and SB provide information about portal and corrected sinusoidal pressure, the morphology of the suprahepatic veins and sinusoids, and the existence of hepatofugal portal circulation. These measures are especially useful in providing hemodynamic and morphological information for surgical treatment. Subhepatic SB, followed by HA, is concluded to be the best diagnostic procedure for PH secondary to cirrhosis.

5130 ENDOGENOUS PLASMA HISTAMINE AND "HEPATOGENIC" GASTRIC ULCER IN LIVER CIRRHOSIS.

(Ger.) Stopik, D.; Hampel, K. E.; v. Kleist, D. (Abteilung fur Innere Medizin mit Schwerpunkt Gastroenterologie, Klinikum Charlottenburg, Freien Universitat, Spandauer Damm 130, 1000 Berlin 19, W. Germany). *Dtsch. Med. Wochenschr.* 102(25):932-933; 1977.

Plasma histamine levels were determined in the venous blood of 10 patients with liver cirrhosis plus solitary or multiple gastric ulcers, 10 patients with stages I-II fatty liver, and 16 normal control subjects. The plasma histamine level averaged 1.3 ± 0.4 µg/l in the patients with liver cirrhosis and gastric ulcer versus 0.7 ± 0.2 µg/l in the controls ($p<0.001$). The level was 0.7 ± 0.3 µg/l in the patients with fatty liver; i.e., it showed no significant difference from controls. The normal liver acts as a filter of plasma histamine, preventing unwanted effects on the systemic circulation. In liver cirrhosis, the elimination of plasma histamine is decreased, suggesting an etiological role of histamine in the genesis of gastric ulcer.

5131 DIAGNOSIS OF NONSUPPURATIVE CHRONIC DESTRUCTIVE CHOLANGITIS (PRIMARY BILIARY CIRRHOSIS). (Ger.) Brunner, G. (Medizinische Universitatsklinik, Humboldtallee 1, 3400 Gottingen, W. Germany). *Dtsch. Med. Wochenschr.* 101(36):1323-1324; 1976.

5132 THERAPY OF NONSUPPURATIVE CHRONIC DESTRUCTIVE CHOLANGITIS (PRIMARY BILIARY CIRRHOSIS). (Ger.) Brunner, G. (Medizinische Universitatsklinik, Humboldtallee 1, 3400 Gottingen, W. Germany). *Dtsch. Med. Wochenschr.* 101(36):1325-1326; 1976.

5133 EFFECT OF PORTACAVAL ANASTOMOSIS ON THE BILE ACID CONCENTRATION IN THE SERUM IN CIRRHOSIS. (Fre.) Poupon, R.; Poupon, R.; Grosdemouge, M. L.; Erlinger, S. (INSERM, Hopital Beaujon, 92110 Clichy, France). *Gastroenterol. Clin. Biol.* 1(4):402; 1977.

5134 TREATMENT OF ENCEPHALOPATHY FOLLOWING PORTAL SHUNT BY SECONDARY ARTERIALIZATION OF THE LIVER IN A CIRRHOTIC PATIENT [Abstract]. (Fre.) Grange, D.; Bismuth, H. (Hopital Paul-Brouss 14, avenue Paul-Vaillant-Couturier, 94800 Villejuif, France). *Gastroenterol. Clin. Biol.* 1(4):402-403; 1977.

5135 LIVER CIRRHOSIS AND HYPERESTROGENISM. (Ger.) Kley, H. K.; Wiegelmann, W.; Nieschlag, E.; Kruskemper, H. L. (2. Medizinische Universitatsklinik und -poliklinik, Moorenstr. 5, 4000 Dusseldorf 1, W. Germany). *Dtsch. Med. Wochenschr.* 101(35):1295-1298; 1976.

5136 SYMPOSIUM ON LIVER CIRRHOSIS WITH PORTAL HYPERTENSION. (Fre.) Weber, I.; Fabre, J. (Departement de medecine, Universite de Geneve, Geneva, Switzerland). *Rev. Fr. Gastroenterol.* (123):11-14; 1976.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

5137 EXTRINSIC ABNORMALITIES AFFECTING THE BILIARY SYSTEM. (Eng.) Ochsner, S. F. (Ochsner Medical Institutions, 1516 Jefferson Highway, New Orleans, LA 70121). *Sem. Roentgenol.* 11 (4):283-287; 1977.

The occurrence of lesions extrinsic to the biliary system causing displacement of its segments is reviewed, and several illustrative cases are discussed. The radiologic pictures of upward displacement of the gallbladder occurring in a woman with a rounded mass filling the right upper abdomen (a renal cyst with renal cell carcinoma) and in a child with a hamartomatous hepatic cyst are presented. Downward displacement of the gallbladder in relation to the biliary ducts is generally the result of a liver neoplasm; as the mass enlarges, it bulges the inferior border of the liver downward. The case of a patient with a right-sided hepatic cyst that displaced the gallbladder downward and also compressed the right biliary ducts is described. A small localized tumor of the liver was demonstrated by a sharp displacement of a small intrahepatic duct. In another case, a huge hepatic hemangioma displaced the biliary tree of the right lobe; the tumor also displaced the common hepatic duct over into the left side of the abdomen and displaced all bile ducts upward. Localized common bile duct displacement is rare, because an enlarging benign process tends to displace a long segment of the duct rather than a short portion of it. However, such displacement is illustrated. Lateral displacement of the common duct is rare, and a case of this type associated with an inflammatory mass due to a surgical sponge is presented. Three examples of medial displacement of the common duct are presented, two of which were due to neoplasms and one of which was caused by a large pancreatic abscess.

5138 GALLBLADDER DISEASE AS A SIDE EFFECT OF DRUGS INFLUENCING LIPID METABOLISM: EXPERIENCE IN THE CORONARY DRUG PROJECT. (Eng.) Gordon, R. S.; Forman, S.; Canner, P.; Berge, K.; Miller, D. (Coronary Drug Project Coordinating Center, Univ. Maryland Sch. Medicine, 600 Wyndhurst Ave., Baltimore, MD 21210). *N. Engl. J. Med.* 296(21): 1185-1190; 1977.

Data obtained during a coronary drug project were analyzed to discover a possible relationship between the treatment of male patients with drugs influencing lipid metabolism and the development of subsequent gallbladder disease. Of 2,680 placebo-treated men who had had myocardial infarction, gallbladder disease developed in 69. In comparison, the frequency of gallbladder disease (cholecystitis or cholelithiasis) among 1,061 men receiving 2.5 mg estrogen, 1,081 men receiving 5.0 mg estrogen, 1,051 men receiving 1.8 g clofibrate, 1,057 men receiving 6.0 mg dextrothyroxine, and 1,069 men receiving 3.0 g nicotinic acid on a daily basis were 46, 47, 42, 23, and 35, resp. The differences in gallbladder disease occurrence between the placebo-treated patients and those treated with either estrogens or clofibrate were statistically significant at the 5% level. A total of 45 variables, including age, body weight, blood pressure, serum lipids, and blood sugar, were evaluated as risk factors among these patient groups. Age significantly correlated with prevalence of known gallbladder disease at entry ($r=0.066$, $p<0.001$). However, no variable yielded a strong and consistent correlation with the incidence of subsequent new gallbladder disease. Gallstone formation is concluded to be a risk whenever clofibrate or estrogens are prescribed.

5139 EFFECT OF INTRAVENOUS FAT EMULSION ON HEPATIC BILE. (Eng.) van der Linden, W.; Nakayama, F. (Dept. Surgery, Centrallasarettet, Ostersund, Sweden). *Acta Chir. Scand.* 142(5):401-406; 1976.

Hepatic bile from 16 patients with nonfunctioning gallbladders who were treated with an i.v. infusion of fat emulsion (20 g glycerol/100 ml) during prolonged preoperative fast was compared with bile from controls. After the infusion of the fat emulsion, rhomboid euhedral tetragonal cholesterol crystals were present in six of eight patients while they were absent in patients treated preoperatively with physiological saline ($p=0.04$). Polygonal crystals (5-30 nm diameter), which showed maltese crosses in polarized light, were also seen in five of eight patients treated with fat emulsion, whereas none were found in controls ($p=0.03$). Hepatic bile from the patients with non-functioning gallbladders treated preoperatively with fat emulsion infusion was found to have a higher mean lithogenic index (0.09 ± 0.12) than that of controls (0.75 ± 0.07). In cholecystectomized patients (8) no euhedral cholesterol crystals were found; however, sporadic presence of polygonal crystals was reported in four patients. It is concluded that infusion of fat resulted in increased lithogenicity of bile in all patients.

5140 BILIARY EXCRETION AND CONCENTRATION OF CEFAZOLIN. (Eng.) Ram, M. D.; Watanatittan, S. (Huron Road Hosp., 13951 Terrace Rd., Cleveland, OH 44112). *Am. J. Gastroenterol.* 66(6):540-545; 1976.

Biliary cefazolin excretion was investigated in 11 patients with cholelithiasis and/or cholecystitis and a radiologically visualized gallbladder, 9 patients with cholelithiasis and a radiologically nonvisualized gallbladder, 5 patients with obstructive jaundice, 5 patients with a T-tube in the common bile duct, and 4 controls. The controls, the patients with obstructive jaundice, and half of the patients with cholelithiasis received 2 g of cefazolin, i.m., in divided doses of 500 mg every 6 hr; the remaining patients received a single dose of 500 mg of the antibiotic i.m. After four injections, the mean cefazolin level in the gallbladder bile of the controls was 127.0 μg/ml. In the patients with cholelithiasis and cholecystitis and a visualized gallbladder, a similar high level was noted (132.0 μg/ml). In the presence of a nonvisualized gallbladder or obstructive jaundice, the cefazolin levels in the bile were lower (30.7 μg/ml in cholelithiasis/chronic cholecystitis with nonvisualized gallbladder). Two hours following a single injection of the drug, the level in the common duct bile reached a peak of 10 μg/ml and at 8 hr it fell to less than 1 μg/ml. In the absence of obstruction, cefazolin reaches a significantly high level in bile and could therefore be valuable in the treatment of biliary infections.

5141 SURGERY OF THE BILIARY TRACT IN GERIATRIC PATIENTS. PARTICULAR FEATURES, MANAGEMENT, RESULTS. (Ger.) Schima, E. (Chirurgische Abteilung, Krankenhaus, Liechtensteinstrasse 67, A-2130 Mistelbach, Austria). *Zentralbl. Chir.* 102(14):858-868; 1977.

Experience with and results of surgery on the gallbladder and bile ducts in 281 patients aged over 70 yr (average 76.1 yr) are presented. Surgery was performed for chronic cholelithiasis in 81 cases, acute cholecystitis in 121, and perforations in 26; operation was performed on the common bile duct in 80, and 15 patients were reoperated. The postoperative mortality was 2/81 in cases of chronic cholelithiasis, 28/185 in cholelithiasis with complications, and 2/15 reoperations. The findings indicate that cholecystectomy for chronic cholelithiasis should be performed even in old age. Acute inflammatory cholecystitis calls for immediate operation. Cholecystectomy is the method of choice, and cholecystostomy is done only in exceptional cases. If there are stones in the common bile duct or stenosis of Oddi's sphincter, acute or perforated cholecystitis is not an impediment to one-stage repair. The indications of transduodenal sphincterotomy are principally the same for all age groups; the postoperative mortality is not higher than that after operations on the common bile duct. The reoperative mortality rate for overlooked stones in the common bile duct or sclerosis of Oddi's sphincter is not higher than that after primary intervention for these conditions.

5142 PROBLEMS OF ATRETIC HEPATOPATHY. PART 2. THERAPEUTIC PROBLEMS. (Spa.) Gubern Salisachs, L. (Instituto Corachan, Barcelona, Spain). *Rev. Esp. Pediatr.* 31(184):613-636; 1975.

The problems of diagnosis and treatment of biliary atresia in infants are reviewed, with emphasis on the work of Japanese clinicians. Early differentiation of neonatal hepatitis and biliary atresia is crucial to subsequent prognosis. Infants with hepatitis should not be treated surgically, while those with extrahepatic atresia must be treated surgically between 4 and 6 weeks of age before the onset of cirrhosis. The relative diagnostic values of standard techniques, such as scintigraphy, cholangiography, elimination of rose bengal with simultaneous cholestyramine administration, laparotomy, and puncture biopsy, are assessed. In spite of the danger of surgical intervention to infants with hepatitis, surgery is recommended if any sign of atresia appears before 3 months of age, as the danger of untreated atresia is greater than the danger of surgery. Surgical techniques (including hepatoportal enterostomy) are described and illustrated, and palliative measures are discussed for incurable cases.

5143 FACTORS AFFECTING BILIRUBIN EXCRETION IN PATIENTS WITH CHOLESTEROL OR PIGMENT GALLSTONES. (Eng.) Shull, S. D.; Wagner, C. I.; Trotman, B. W.; Soloway, R. D. (Hosp. Univ. Pennsylvania, 3600 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 72(4):625-629; 1977.

To identify factors affecting bilirubin excretion, the effects of bile flow and bile salt excretion on bilirubin output into bile were examined in eight patients with cholesterol (CS) and two patients with pigment (PS) gallstones. All patients were normobilirubinemic and cholecystectomized with balloon-occludable, reinfusion T-tubes. Another patient with PS, sickle cell disease (SS), and stable jaundice was studied to examine the mechanism by which an increased bilirubin load was excreted. Total bilirubin was almost entirely conjugated, and excretion was related linearly to bile salt excretion in PS and CS patients; one-third of bilirubin excretion was bile salt-independent and two-thirds were bile salt-associated. In the SS patient, 90% of the bilirubin excretion was independent of bile salt output. In PS and CS patients, bilirubin output was linearly related to bile flow, but the SS patient showed significant bilirubin excretion at low flow rates. CS and PS patients had similar patterns of bilirubin excretion, but the increased bilirubin load in the SS patient was excreted entirely independently of bile salts. In the SS patient, unconjugated bilirubin output was hyperbolically related to bile salt output and represented a maximum of 3% of the total bilirubin output. The bile salt-independent excretion of conjugated bilirubin suggests that micelles were not required for transport into bile, whereas the hyperbolic relation for unconjugated bilirubin and bile salt output (similar to that of the micellar lipids, cholesterol, and phospholipids) suggests interaction with micelles.

5144 THE USE OF d-LIMONENE PREPARATION AS A DISSOLVING AGENT OF GALLSTONES. (Eng.) Igim H.; Hisatsugu, T.; Nishimura, M. (First Dept. Surger Faculty Medicine, Fukuoka Univ., Fukuoka, Japan). *Am. J. Dig. Dis.* 21(11):926-939; 1976.

The value of a *d*-limonene preparation for gallstone dissolution was tested in *in vitro* and *in situ* solubility studies, and clinical studies were undertaken after toxicity, pharmacodynamic, and metabolic studies confirmed its safety. *In vitro*, a mixture of 97.0 parts *d*-limonene, 2.1 parts polysorbate 80, and 0.9 parts sorbitan mono-oleate completely dissolved a pure cholesterol stone within 2 hr, two cholesterol-pigment-calcium stones in 2 hr (by 85.4% and 90.1%, resp.), a bile pigment-calcium stone in less than 150 hr (16.8%), and a fatty acid-calcium stone in about 6 hr (25.2%). Five healthy volunteer received *d*-limonene (20 g) p.o., and the following examinations were undertaken: liver function (total protein, A/G, TTT, ZTT, total bilirubin, total cholesterol, SGOT, SGPT, and alkaline phosphatase), urinalysis, kidney function (blood urea nitrogen), and pancreatic function (amylase). None were abnorm except that minor proteinuria was seen transiently in each patient. All volunteers complained of mild diarrhea and tenesmus. The preparation was tested in 15 patients whose surgically removed stones had dissolved *in vitro* with this procedure; all patients were subsequently found to have retained stones in the common or hepatic duct after surgery. Three weeks postoperatively, the choledochal drain was removed and replaced immediately by a rubber cathete chemically resistant to *d*-limonene. The end of the tube was directed to the stones using a guidewire. Twenty milliliters of *d*-limonene was injected for a period of 30 min or longer, and the drain was clampe for 0.5-2 hr to keep the preparation in contact with the stones; this procedure was usually carried out every other day. In 14 cases, 3 of which are presented in detail, the third to 25th infusion was effective in dissolving retained stones. The stones in all these patients contained 70% or more cholesterol. In one of the successful cases, the dissolving effect of the preparation was clearly evident; four stones in the common bile duct were dissolved first, and the stone lodged in the duodena papilla disappeared finally. This procedure may be carried out as an adjunct of the mechanical lithotom or as a unique technique when the mechanical method may not be suitable.

45 DISSOLUTION OF RETAINED CHOLEDOCHAL
CALCULI. (Eng.) Wheeler, M. H. (Univ.
sp. Wales, Cardiff, Wales). *Ann. R. Coll. Surg.*
gl. 59(2):153-157; 1977.

e history of the technique of promoting dissolu-
on of retained gallstones in the biliary tree is
iefly reviewed, and experience with six patients
th retained choledochal calculi is presented.
ese patients were treated by common duct infusion
heparinized saline and/or sodium cholate for
-28 days. Successful gallstone dissolution was
hieved in five patients, one of whom developed
evere pancreatitis and renal failure responsive
peritoneal dialysis. Other complications in
ese patients included diarrhea and vomiting.
e one failure was in a patient whose retained
tone was situated in the left hepatic duct. This
ethod is a valuable alternative to re-exploration
f the common bile duct, particularly when calculi
re situated in the distal part of the duct.

146 CHOLEDOCHAL CYST IN INFANCY AND CHILDHOOD:
ANALYSIS OF 16 CASES. (Eng.) Kobayashi,
.; Ohbe, Y. (Natl. Children's Hosp., Taishido 3-35-
1, Setagaya-ku, 154 Tokyo, Japan). *Arch. Dis.*
hild. 52(2):121-128; 1977.

he clinical features of 16 infants and children
ith choledochal cysts are described, and the case
eports of seven patients are presented. Choledo-
hal cyst was diagnosed before operation in 14 out
f 16 patients by means of a combination of diag-
ostic tests. Ultrasonic echogram showed a cystic
ass in all 11 patients examined. The character-
stic displacement of the duodenum was noted in 9
f 14 patients by contrast studies of the upper
astrointestinal tract, and hepatobiliary scinti-
canning confirmed choledochal cyst in 7 of 8 pa-
ients. A cyst was shown by p.o. or i.v. cholangio-
raphy in three of four patients. In 16 patients, the
nset of symptoms occurred from 7 days of age to 9.5
r; in 10 patients onset occurred under 12 months of
ge, in 3, from 13 to 24 months, and in the remaining
, from 2 to 9.5 yr. The first symptoms were jaun-
ice, vomiting, acholic stools, and poor sucking.
bstructive jaundice and acholic stools were found
in over 80% of the patients, and abdominal mass in
60%. Vomiting occurred in 50% of the patients,
one-third of whom showed failure to thrive, and
70% of patients over the age of 1.5 yr had abdom-
inal pain. About half of the patients had a mild
to moderate degree of fever. In all patients,
primary excision of the cyst was followed by hep-
aticojejunostomy in Roux-en-Y fashion. The post-
operative course was uneventful in 14 patients;
2 patients died, one from ascending cholangitis and
one from hepatic failure. When choledochal cyst
is suspected, the following diagnostic procedures
are necessary to confirm the diagnosis, in this
order: ultrasonic echography, roentgenological
studies of the upper gastrointestinal tract, and
hepatobiliary scintiscanning.

5147 BACTERIOLOGICAL STUDY OF BILE IN CHOLELITHIASIS (REPORT OF 177 CASES). (Fre.) Grimoud, M.; Izard, G.; Lazorthes, F.; Lemozy, J. (No affiliation given). *Bull. Acad. Natl. Med. (Paris)* 160(2):203-207; 1976.

A bacteriological study of preoperative bile samples from 177 patients with cholelithiasis revealed positive cultures in 105. Gram-negative bacteria was the most frequently encountered group of flora: *Escherichia coli* (48), *Klebsiella pneumoniae* (29), *Proteus* (6), group B *Salmonella* (wien) (1), *Pseudomonas aeruginosa* and other bacteria (8), and *Acinetobacter calcoaceticus* (3). Other organisms found included *Streptococcus faecalis* (7), *Staphylococcus aureus* (2), and *Candida tropicalis* (1). External drainage (Kehr procedure) was the cause of infection in 14 cases, and the frequency of positive cultures paralleled the age of the patients. Findings were positive in 50% of the patients aged <70 yr and in 73-90% of patients aged 70-80 yr. A relation between bile infection and postoperative morbidity was also noted: 53/105 patients developed parietal or deep abscess, septicemia, bronchial or urinary tract infection, or isolated hyperthermia, compared with only 12/72 patients with negative cultures. The highest incidence of positive cultures also occurred in patients with acute cholecystitis (62%) and bile duct lithiasis (64%); cultures of 47% of the patients with chronic cholecystitis were positive. It was concluded that even exploratory choledochotomy would triple the incidence of postoperative morbidity. Proper antibiotic therapy should be instituted prior to exploratory procedures.

5148 BILIRUBIN URIDINE DIPHOSPHATE-GLUCURONOSYLTRANSFERASE DEFICIT IN THE LIVER AND CHOLELITHIASIS. (Fre.) Duvaldestin, P.; Metreau, J. M.; Preaux, A. M.; Merthelot, P. (INSERM U-99, Hopital Henri-Mondor, F 94010 Creteil, France). *Biol. Gastroenterol. (Paris)* 9:338; 1976.

The relation between the occurrence of certain bladder calculi and bilirubin uridine diphosphate-glucuronosyltransferase (BUDP-GT) levels was investigated in 37 adults with biliary lithiasis (BL) and in 33 control subjects. BUDP-GT levels were low (<0.600 mg conjugated bilirubin/hr/g liver) in 13/37 patients (7/10 men and 6/27 women), but in only 1/33 controls. Pathological BUDP-GT levels occurred more frequently in the younger patients (9/16 of those <50 yr of age). The distribution of age and sex differs in cholesterolic lithiasis. There may be a relation between BUDP-GT deficiency and the presence of certain biliary calculi.

5149 RESULTS OF THE TREATMENT OF CHOLELITHIASIS AND ITS CONSEQUENCES: THE SO-CALLED "POST-CHOLECYSTECTONY SYNDROME". (Ger.) Kothe, W.; Mlynek, H. J.; Schenker, U. (Chirurgische Klinik des Bereichs Medizin, Karl-Marx-Universitat, Liebigstrasse 20a, DDR-701 Leipzig, E. Germany). *Zentralbl. Chir.* 101(18):1125-1135; 1976.

Surgical results in patients with gallbladder and bile duct diseases are presented. A group of 146 patients underwent cholecystectomy for cholelithiasis (group 1), 122 underwent choledochotomy for choledocholithiasis (group 2), and 110 underwent sphincterotomy for papillary stenosis (group 3). The cure rate was 81% in group 1, 69% in group 2, and 75% in group 3. There was considerable improvement in 15% of group 1, 22% of group 2, and 17% of group 3 patients; these patients did not have serious complaints and they were able to work. Slight improvement was achieved in 4% of group 1, 9% of group 2, and 8% of group 3 patients. The major complications and complaints among the patients showing moderate to slight improvement included hypochlorhydria, hyperchlorhydria, biliary dyskinesia, and cholangiohepatitis, along with atrophic gastritis, hiatal hernia, gastric ulcer, duodenal ulcer, duodenal diverticulum, liver cirrhosis, fatty liver, chronic pancreatitis, adhesions, and postoperative hernia. The incidence and intensity of the postoperative complications increased with the length and seriousness of the primary disease. Postoperative mortality was 0.95% due to cholelithiasis, 14% due to choledocholithiasis, 11.1% due to papillary stenosis, 14.6% due to choledigestive fistula, 22.2% due to perforating cholecystitis, 36% due to gallstone ileus, 8% due to lesion of the common bile duct, and 10.7% due to complications after reoperation. The findings indicate the necessity of early surgical treatment of cholelithiasis and of the exact preoperative diagnosis of other abdominal organs.

5150 THE POSTCHOLECYSTECTOMY SYNDROME. PROPHYLAXIS AND THERAPY. (Ger.) Grill, W. (Chirurgische Abteilung des Kreiskrankenhauses, Osswaldstr. 1, D-8130 Starnberg, W. Germany). *Munch. Med. Wochenschr.* 119(17):569-572; 1977.

The problems, prophylaxis, and treatment of postcholecystectomy syndrome, based on 2,890 procedures performed over an 11-yr period, are presented. Overall, 360 multiple procedures were performed for unrecognized bile duct stones and papillary stenoses, which indicated that the bile duct disorders were not confined to the gallbladder, but had spread to the drainage bile ducts. The primary prophylaxis for postcholecystectomy syndrome is early surgery to stop the disease spreading to the drainage bile ducts, papilla, and pancreas. Discrete epigastric pain was frequent, which is not indicative of gallstone disease; one-fifth of the operated patients 60 yr and above had been treated for gastritis. Intraoperative radiomanometry (determination of pressure and x-ray picture of the bile ducts) is recommended prior to surgery. Leftover cystic stumps with neuromas, remainders of gallbladder, and concrements also required repeat surgery. In these instances, endoscopic retrograde cholangiography was decisive, but the detection of papillary stenoses can also be problematic with this procedure, and transduodenal sphincterotomy is indicated. Surgical reintervention was performed in 43 patients because of falsely indicated choledochoduodenostomy and subsequent cholangiophytiasis. Villous polyps or carcinoma of the bile duct were also found. In the former cases, local excision was performed, whereas a duodenohemipancreatectomy (Whipple's operation) was carried out for carcinoma of the papilla. Cystojejunostomies were done in patients with pseudocysts of the head of the pancreas. Cholangio- and pancreaticography was indicated in patients wit severe chronic pancreatitis, followed by a distal hemipancreatectomy and opening of the pancreatic duct. Hydatid cysts of the liver were totally excised on several occasions.

5151 REOPERATION OF THE BILE DUCTS. (Ger.) Sery, Z.; Duda, M.; Kral, V.; Manak, P. (I. Chirurgische Universitatsklinik, I. P. Pavlova 6, Olomouc, Czechoslovakia). *Zentralbl. Chir.* 102 (14):851-857; 1977.

The causes and results of bile duct reoperation among a total of 5,560 primary interventions (performed from 1951 to 1975) are reviewed. Reoperatio was necessary shortly after papillosphincterotomy in 21/654 patients because of inflammation (17, 4 of whom died postoperatively) and gastrointestina hemorrhage (4, all of whom survived). Another 24 patients had to be reoperated within 7 yr as a result of choledocholithiasis in 11 patients, stenosi of the ampulla of Vater in 6, and other causes in 7 The 11 choledocholithiasis patients underwent resphincterotomy with stone extraction (8), stone extraction by choledochotomy (1), and stone extractio with choledochojejunal anastomosis (2). The six recurrent stenosis patients underwent resphincterotomy (3), or choledochoduodenal anastomosis (3). A total of 84 reoperations were performed on 35 patients for iatrogenic stricture of the bile ducts surgery consisted of choledochoduodenojejunal anastomosis in 6 patients (8 operations, mortality 0/6) hepaticoduodenal anastomosis in 9 (17 operations, mortality 1/9), hepaticojejunal anastomosis in 10 (27 operations, mortality 1/10), diahepatic drainage according to Smith in 8 (28 interventions, mortality 0/8), and various interventions in 2 (4 interventions, mortality 0/2).

5152 PORCELAIN GALLBLADDER (CHOLECYSTOPATHY WITH LIMY BILE). (Spa.) Cuartero, A. R. Garcia, M. M. (Facultad de Medicina, Hospital Clin ico de "San Cecilio," Universidad de Granada, Granada, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(3): 387-392; 1976.

Cholecystopathy with limy bile was discovered in a 48-yr-old man who presented with gastric dyspepsia without history of hepatobiliary dysfunction. This disorder can only be diagnosed by simple radiograph and it is often found accidentally in the course of gastric exploration. Without contrast medium, the calcium-rich gallbladder produces a radiopaque shadow with transparent zones (cholesterol calculi) Treatment is usually surgical. In reported cases, 86.5/100 are women and 13.5/100 are men. Etiology, clinical signs, and occurrence of this rare disorde are briefly reviewed.

5153 LATE STENOSIS OF THE INTERMEDIATE COMMON BILE DUCT. (Spa.) Bergalli, L. E.; Piacenza, G.; Chifflet, J.; Gateno, N.; Estefan,

A.; Priario, J. C.; Praderi, R. C. (Republica Dominicana 2922, Montevideo, Spain). *Cir. Uruguay* 45(3):189-191; 1975.

Three cases are presented in which stenosis of the intermediate common bile duct occurred several years after biliary tract surgery. Two patients had undergone cholecystectomy for biliary lithiasis, and the other had undergone choledochotomy for removal of a 3-cm calculus. The patients presented with several episodes of jaundice 5-12 yr later, sometimes accompanied by fever, acute abdomen, acholia, or choluria. These symptoms prompted erroneous diagnoses of hepatitis, residual choledochal lithiasis, and neoplasm of the pancreas. Surgery revealed non-neoplastic fibrosclerotic strictures of the bile duct in all three cases. Choledochal resection was repaired by end-to-side hepatojejunal anastomosis or by reconstruction of the biliary duct, in each case reinforced by a tube. Good recovery was reported in two of three patients.

5154 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATICOGRAPHY (ERCP). (Ger.) Koch, H.; Schneider, A.; Rosch, W.; Schaffner, O. (Medizinische Univ.-Klinik, 852 Erlangen, W. Germany). *Aktuel. Chir.* 12(2):91-102; 1977.

Endoscopic retrograde cholangiopancreaticography (ERCP) was performed in 2,595 patients for suspected pancreatic disease (550 patients), common bile duct disease (833), pancreatic and common bile duct disease (119), and subjective abdominal complaints (1,093). The diagnostic results were chronic pancreatitis in 55 patients, pancreatic carcinoma in 104, calculi in the biliary tract in 731, and normal findings in 1,100. The success rate of ERCP was 83.9% in the pancreatic duct and 74.1% in the biliary tract. Thirty-four patients developed acute pancreatitis following ERCP, 8 of whom had preexisting disease of the pancreas and 22 had preexisting disease of the bile ducts. The pancreatitis was fatal in five patients: an infected pseudocyst was the cause of death in one, total pancreatic necrosis in the others. ERCP should be the last diagnostic procedure employed to clarify surgical indications. Early ERCP is indicated in biliary tract diseases.

5155 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY IN DIAGNOSTIC EVALUATION OF 160 JAUNDICED PATIENTS. RESULTS OF AN IMPROVED TECHNIC. (Eng.) Burcharth, F.; Christiansen, L.; Efsen, F.; Nielbo, N.; Stage, P. (Herlev Hosp., Univ. Copenhagen, 2730 Herlev, Copenhagen, Denmark). *Am. J. Surg.* 133(5):559-561; 1977.

Percutaneous transhepatic cholangiography (PTC) was carried out in 160 patients using an improved technique. Selective catheterization is employed, with introduction of the catheter in the right midaxillary line at the level of the 12th thoracic vertebra. In patients with biliary obstruction, the catheter is left indwelling centrally in the biliary passages for external bile drainage; thus, the investigation does not necessitate immediate operation in these patients. The biliary tree was visualized in 139 patients, and the biliary tree and the obstruction were disclosed by PTC in 113 of the 115 patients with surgically or autopsy proven obstruction. Suspicion of obstruction was ruled out in 45 patients; normal bile ducts were demonstrated in 26 of these, and the biliary tree could not be visualized in 19 patients. Complications occurred in six patients, but these were not exclusively due to PTC; they included bile leakage, hepatoduodenal ligament edema, and intra-abdominal bleeding (due to tearing out the catheter in mentally confused patients). PTC may be useful in the differential diagnosis between obstructive and nonobstructive jaundice, and laparotomy can be frequently avoided.

5156 ULTRASONIC INVESTIGATIONS IN OBSTRUCTIVE BILIARY TRACT DISEASES. (Ger.) Frommhold, H.; Koischwitz, D. (Radiologische Universitatsklinik, 5300 Bonn 1, Venusberg, W. Germany). *Dtsch. Med. Wochenschr.* 102(2):62-63; 1977.

Ultrasonic echography is particularly useful when x-ray studies cannot be carried out, as in severe damage of the liver parenchyma, hyperbilirubinemia, and obstructive dilatation of the gallbladder. Knowledge of normal sonotomography is necessary to diagnose any pathological changes. The locations of the aorta, vena cava, and portal vein serve as reference points. The gallbladder is recognized as a cystic structure with a homogeneous, echo-free space and sharply defined border echoes within the liver parenchyma. Echographic diagnosis of gallbladder hydrops, based on the clear difference in impedance between the gallbladder wall and the increased gallbladder contents, is usually made easily. Longitudinal and transverse sections must be combined for gallstones to be demonstrated. The reflection of the gallbladder must be differentiated from that of an echinococcus cyst, liquefied hematoma, or liver abscess. Echographic diagnosis of the extended intra- and extrahepatic bile discharge pathway is more difficult, requiring systematic transverse sections of the liver between the xiphoid and the navel, with 20- to 25-mm sections, which are usually differentiated by exact analysis of the ribbonlike contours of the intrahepatic portal vein branches. In obstructive diseases of the pancreas, attention must be paid to the biliary system.

5157 ULTRASONOGRAPHY IN OBSTRUCTIVE JAUNDICE. (Eng.) Malini, S.; Sabel, J. (Texas Medical Center, Houston, TX 77030). *Radiology* 123 (2):429-433; 1977.

The accuracy of ultrasonic examination in differentiating obstructive jaundice from nonobstructive jaundice and in delineating the site of obstruction was evaluated in 35 patients. The diagnosis was substantiated by laparotomy, autopsy, or liver biopsy. Eighty-six percent of the 35 jaundiced patients were correctly identified as having either obstructive or hepatocellular jaundice. There were three false negative and two false positive examinations. The site of obstruction was accurately identified in 85% of the patients as being (a) at the level of the proximal bile duct or porta hepatis, or (b) at the level of the distal bile duct or pancreas. The criteria for the diagnosis of obstructed bile ducts were the finding of an enlarged common bile duct above 1 cm in diameter, or the presence of multiple intrahepatic bile ducts measuring 4 mm and above. Radionuclide imaging of the liver was carried out in 30 cases; the image was normal in 1 case. Obstructive jaundice was noted in 22 patients; 8 of these, who were reported to have an enlarged porta hepatis, were found to have surgical obstruction. In the remaining 14 patients, diffuse patchy uptake was reported in 12 examinations. Abdominal ultrasound is useful in the evaluation of jaundice and the diagnosis of obstruction, and it is recommended as a preliminary study in the evaluation of jaundice.

5158 LIPOPROTEIN X (LP-X) IN THE DIAGNOSIS OF THE CHOLESTASIS SYNDROME. AN OVERVIEW OF CURRENT METHODS OF DETECTION AND DETERMINATION AS WELL AS CLINICAL IMPORTANCE. (Ger.) Kerber, Ch.; Ehrke, D.; Storm, H.; Linneke, P. (Abteilung fur Gastroenterologie und Hamatologie der Medizinischen Klinik des Bezirkskrankenhaus, Wismarsche Strasse 298, DDR-27 Schwerin, E. Germany). *Dtsch. Gesundheitsw.* 31(45):2153-2157; 1976.

Studies of the detection, determination, and diagnostic value of lipoprotein X (LP-X) in the cholestasis syndrome are reviewed. LP-X can be detected by ultracentrifugation, gel precipitation, or by a more complicated method with monospecific antiserum to LP-X. Quantitative determination is possible by determination of free cholesterol or phospholipids in the LP-X fraction on the basis of the constant composition of LP-X, by electroimmunodiffusion, radical immunodiffusion, or by direct densitometry following precipitation and electrophoretic separation. LP-X is the most reliable of all biochemical parameters available for the diagnosis of cholestasis. However, it does not permit differential diagnosis between the intrahepatic and extrahepatic forms. There is no correlation between positive LP-X test and the presence of hepatitis B antigen. Serum LP-X is sharply reduced or it disappears following heparin injection *in vivo*.

5159 ABNORMAL LIPOPROTEIN (LP-X) IN THE FIRST MONTHS OF LIFE WITH PARTICULAR REFERENCE TO OBSTRUCTIVE JAUNDICE. (Ger.) Lachmann, D. (Universitats-Kinderklinik, Wahringer Gurtel 74-76, A-1090, Vienna, Austria). *Wien. Klin. Wochenschr.* 89(Suppl. 69):1-28; 1977.

Lipoprotein (LP) levels were measured in over 2,000 sera from more than 370 premature and mature newborns to detect obstructive jaundice. Quantitative, qualitative and semiquantitative (Rapidophor method)
measurements of LP were made; cholesterol, trigly
cerides, bilirubin, and serum enzyme activities
(SGGT, alkaline phosphatase) were also measured.
A study of 270 of the infants, aged up to 16 week
showed that 268 had abnormal LP levels. Of 80 co
trols, aged 4-12 months, abnormal LP levels were
detected in 8. Fifty-four percent of the abnorma
LP levels were found in infants 1-7 days old, whe
as this increased to 86% for infants 2 weeks old.
No correlation was found between alkaline phospha
tase, SGGT, bilirubin, and abnormal LP levels. T
frequency of abnormal LP levels was greatest in i
fants with liver diseases (85%), followed by earl
birth (83%), diabetic fetopathies (80%), blood
group incompatibility (73%), hyperbilirubinemia
(75%), pulmonary diseases (76%), cardiac valve de
fects (72%), birth trauma (70%), small sized babi
(67%), malformations (65%), mucoviscidosis (57%),
neurological diseases (56%), and gastrointestinal
diseases (36%). No abnormal LP levels were found
in 30 healthy pregnant women or in cord blood at
the time of birth. The LP levels did not depend
on the type of nourishment taken. Babies weighin
less than 1,500 g had markedly higher LP levels
than those between 1,500 and 2,500 g and fullterm
infants. LP levels returned to normal after 7 we
of age. In six infants with proven obstructive
jaundice, the LP levels during the acute stage
ranged from 56 to 112 mg/100 ml, and in one infan
it increased to 900 mg/100 ml. The bilirubin lev
ranged from 5.6 to 19.7 mg/100 ml. Four of the s
infants survived, and LP levels returned to norma
during the 5-10th week. The causes of obstructiv
jaundice included cholestasis with intrahepatic b
duct hyperplasia, premature birth, giant cell hep
titis, hepatitis with sepsis, and extrahepatic
atresia. It is suggested that high LP levels may
be due to a cholestatic type of mechanism, a defi
ciency in the cholesterol-acetyltransferase syste
or an insufficient supply of lipoprotein lipase,
which catalyzes LP.

5160 COMPRESSION OF THE RETROPANCREATIC BILE
DUCT BY A MASS OF TUBERCULOUS LYMPH NOD
CAUSING OBSTRUCTIVE JAUNDICE. (Fre.) Martinon,
Aurousseau, R. (Hopital Laennec, 42, rue de Sevre
75 Paris, France). *J. Chir. (Paris)* 112(3):145-
152; 1976.

Tuberculosis of the retroduodenopancreatic lymph
nodes was found in a 28-yr-old African man with n
previous medical history. The enlarged nodes com
pressed the retropancreatic bile duct, causing a
severe obstructive icterus. Since this rare type
of tuberculosis is almost always a primary infec-
tion, the correct diagnosis is difficult and usu-
ally only becomes apparent during exploratory sur
gery. A simple biliary bypass was performed, sin
the removal of the tuberculous nodes carried a
high risk. Antitubercular drugs were administere
for 18 months postoperatively, and a total cure w
achieved.

5161 POSTOPERATIVE JAUNDICE. REPORT OF 14
CASES. (Fre.) de Blonay, J. (Departeme

Chirurgie, Hopital Cantonal universitaire de
eve, Clinique chirurgicale universitaire, 1211
eva 4, Switzerland). *Sem. Hop. Paris* 53(3):
-189; 1977.

toperative jaundice (PJ) developed in 14/1,027
ients following surgical intervention for hepatic,
iary, pancreatic, and gastrointestinal diseases.
time of appearance of PJ ranged from 2 to 11
s postsurgery, and the mean duration was 11.6
s. Surgical, medical, and indirect factors were
sidered. The peritoneum was opened in all the
ients. Six of the patients had received halothane,
ch tripled the bilirubin level. Two patients
received multiple treatments, and PJ was
ributed solely to promethazine in one. Anoxia
have been a factor in three patients, along
h sepsis and fever. An excess of biliary pig-
t, viral and intercurrent serum hepatitis, and
enteral alimentation may also have been contri-
ory factors. Four of the 14 patients who
eloped PJ died: massive steatosis developed in
atient, another showed a histologically normal
er at autopsy, 1 had cholestasis of the liver,
no autopsy could be performed in the fourth.
10 remaining patients were cured.

52 CLINICALLY UNDIAGNOSED GLYCOGEN STORAGE DISEASE TYPE I AS A CAUSE OF POSTOPERATIVE
TH. (Ger.) Nier, H.; Sailer, R.; Muntefering,
(Chirurgische Klinik und Poliklinik der Univer-
at, Moorenstrasse 5, 4000 Dusseldorf 1, W. Ger-
y). *Dtsch. Med. Wochenschr.* 102(12):433-435;
7.

30-yr-old woman underwent cholecystectomy with a
tative diagnosis of complete obstruction of the
stic duct. The preoperative clinical and biochem-
l findings (serum electrolytes, RBC, WBC, bil-
ubin, alkaline phosphatases, serum transaminases,
diastase) were normal. Calculi were found in
gallbladder, but not in the cystic duct or in
her sections of the biliary tract. The patient
ddenly developed cardiac and respiratory arrest
out 3 hr after awakening from the anesthesia.
patient was revived, but she died of another
tack on the following morning. Blood serum taken
ring reanimation had a potassium level of 2.6 mmol/
1, an oxygen pressure of 34.8 mm Hg, and a pH of 6.96. Pronounced type I glycogen storage disease, with glycogen deposits in all liver cells and in the tubular epithelium of the kidneys, was found at autopsy. Hypoglycemia and metabolic acidosis were assumed to have led to hypokalemia, which was considered the cause of cardiac failure.

5163 THE SIGNIFICANCE OF THE NON-VISUALIZED GALLBLADDER AT TRANSHEPATIC CHOLANGIOGRAPHY (THC) [Abstract]. (Eng.) Johnson, G. H.; Halls, J.; Douglas, A. P. (Dept. Medicine, Univ. Southern California, Los Angeles, CA). *Clin. Res.* 25(2):110A; 1977.

5164 SOME PROBLEMS OF BILIARY TRACT SURGERY. (Eng.) Ong, G. B. (Dept. Surgery, Univ. Hong Kong, Hong Kong). *J. R. Coll. Surg. Edinb.* 22(1):9-18; 1977.

5165 CONGENITAL CYSTIC DILATATION OF THE COMMON BILE DUCT: RELATIONSHIP TO ANOMALOUS PANCREATICOBILIARY DUCTAL UNION. (Eng.) Kimura, K.; Ohto, M.; Ono, T.; Tsuchiya, Y.; Saisho, H.; Kawamura, K.; *et al.* (Chiba Univ. Sch. Medicine, Chiba [280], Japan). *Am. J. Roentgenol.* 128(4):571-577; 1977.

5166 THE MANAGEMENT OF GALLSTONE ILEUS. (Eng.) Mackenney, R. P. (Stoke Mandeville Hosp., Aylesbury, Bucks, England). *J. R. Coll. Surg. Edinb.* 21(5):292-295; 1976.

GENERAL

67 BEHCET DISEASE AND THE HLA SYSTEM. (Eng.) Takano, M.; Miyajima, T.; Kiuchi, M.;
mori, K.; Amemiya, H.; Yokoyama, T.; *et al.* (Dept.
rmatology, Chiba Univ., 1-8-1 Inohana, Chiba,
pan). *Tissue Antigens* 8(2):95-99; 1976.

microdroplet lymphocytotoxicity test was used to
issue type for 26 antigens of the HLA system in
3 unrelated patients with Behcet's syndrome and in
3 members of seven families with at least 2 patients
er family. Among 17 patients with complete type
isease, which included all four major clinical
manifestations (aphta, skin, genital, and occular lesions), 88.2% had HLA-B5 as compared with 38.3% for controls (corrected p=0.0052). For 37 patients with incomplete type disease (at least three of the above lesions or both ocular lesion and the other two clinical manifestations), 8 patients with probable disease (two lesions not including occular lesions), and 11 patients with possible disease (only aphta), the corrected p value was not significant, although B5 was more frequent in patients with incomplete disease than in controls. The incidence of HLA-B5 was more common in male

patients than in females, being 9/9, 6/9, 2/5, and 2/4 for complete, incomplete, probable, and possible type disease, resp., versus 6/8, 16/28, 0/3, and 2/7 for female patients with the above disease types, resp. The family studies showed that, in three families, all of the patients had haplotypes containing B5 that were common to the patients in the respective families. In three other families, the patients had particular haplotypes associated with disease type, although they did not have B5. In one of these three families, the incomplete type patients had a particular haplotype (9, BW40) that the possible type patients did not have; in another family, the probable type patients had a particular haplotype (AW30, 7) that the possible type patients did not have. In the seventh family, this particular haplotype did not exist in the incomplete type patients. The family studies suggest that the genes closely linked to the HLA locus influence the severity of Behcet disease.

5168 EXOCRINE PANCREATIC FUNCTION IN JUVENILE-ONSET DIABETES MELLITUS.

(Eng.) Frier, B. M.; Saunders, J. H. B.; Wormsley, K. G.; Bouchier, I. A. D. (Ninewells Hosp. Medical Sch., Univ. Dundee, Dundee, Scotland). *Gut* 17(9):685-691; 1976.

Exocrine pancreatic function was studied in juvenile-onset diabetics (20), maturity-onset diabetics (7), patients with diabetes secondary to chronic pancreatitis (5), and 13 nondiabetic controls to establish the frequency of exocrine pancreatic dysfunction and its relation to the degree of impairment and duration of the disease. The exocrine pancreatic secretory capacity was reported to be reduced in 80% of insulin-dependent diabetics, and the degree of dysfunction increased with the duration of the disease. The outputs of bicarbonate (all patients), trypsin (80% of patients), and amylase (65% of patients) were significantly reduced in diabetic patients in response to i.v. secretin (1 clinical U/kg/hr) and cholecystokinin-pancreozymin (1 Ivy U/kg/hr). The output of bicarbonate in patients with less than 10 yr of diabetes showed an inverse relation ($p < 0.0125$) with the total daily insulin dosage required for control of the disease. The extent of exocrine pancreatic secretory insufficiency was reported to be related to the duration of the disease in the juvenile-onset group. Five patients with chronic pancreatitis had severe steatorrhea, indicating destruction of about 90% of the exocrine secretory capacity. It is concluded that reduction in pancreatic secretory capacity is significant and must be taken into consideration when interpreting pancreatic exocrine function in diabetics.

5169 STOOL BACTERIAL AEROBIC OVERGROWTH IN THE SMALL INTESTINE OF CHILDREN WITH ACUTE DIARRHOEA.

(Eng.) Neto, U. F.; Toccalino, H.; Dujovney, F. ([U.F.N.] Rua Luiziana, 129-Casa 4, Brooklyn Paulista, Sao Paulo, Brazil). *Acta Paediatr. Scand.* 65(5):609-615; 1976.

The aerobic flora of 22 children (ages 40 days t
months) with malnutrition and acute diarrhea and
well-nourished children (ages 45 days to 9 months
with acute diarrhea were examined by intubation
the upper and middle small intestine and by stool
culture. In 18 of the 22 children with malnutrit
material for bacteriological study was obtained
the upper small intestine; growth was 10^4 bacter
(2 cases), 10^5/ml (2 cases), 10^6/ml (2 cases), a
10^7/ml (12 cases). Culture material obtained fr
the middle small intestine in 17 cases showed gr
of 10^5 bacteria/ml (3 cases), 10^6/ml (4 cases),
10^7/ml (10 cases). Enteropathogenous bacteria w
concomitantly observed in the small intestine an
in stool culture in six cases; they were isolate
exclusively in stool culture in two cases and ex
sively in the small intestine in one case. Samp
of the upper small intestine from three of five
nourished children showed growths of 10^3 bacteri
10^5/ml, and 10^7/ml, resp. Culture material from
middle small intestine of all five children show
growths of 10^5 bacteria/ml (1 case), 10^6/ml (1 c
and 10^7/ml (3 cases). Enteropathogenous *Escheri*
coli was isolated in only one case and exclusive
from the stool culture. In contrast to the abov
results, there was no aerobic flora development
of 11 healthy controls (ages 7 months to 8 yr);
aerobic flora development was observed, concentr
tions did not surpass 10^4 bacteria/ml. It is su
gested that the elevated incidence of overgrowth
small intestinal aerobic flora in children with
acute diarrhea may play an important role in the
pathology of this disorder.

5170 EPIDEMIC DIARRHEA AT CRATER LAKE FROM TEROTOXIGENIC Escherichia coli. A LAR WATERBORNE OUTBREAK.

(Eng.) Rosenberg, M. L.; Koplan, J. P.; Wachsmuth, I. K.; Wells, J. G.; Gangarosa, E. J.; Guerrant, R. L.; Sack, D. A. (Center for Disease Control, Atlanta, GA 30333). *Ann. Intern. Med.* 86(6):714-718; 1977.

An epidemiologic study of an outbreak of diarrhe
caused by contaminated water is reported. In Ju
and July 1975, gastrointestinal illness occurred
more than 200 staff members and 2,000 visitors t
an American national park. It was characterized
prolonged diarrhea, cramps, nausea, and vomiting
lasted a median duration of 8 days; and was sig-
nificantly associated with consumption of park w
($p < 0.001$) that had been contaminated by raw sewa
Enterotoxigenic *Escherichia coli* serotype 06:K15
was isolated from 20/49 ill park residents and f
the park's water supply, but not from 71 residen
who had never been ill or had been well for at
least 4 days. No other bacterial, viral, or par
sitic pathogens were isolated from ill or well p
sons. This outbreak is the first waterborne epi
demic of diarrheal illness shown to be due to en
otoxigenic *E. coli*, and this study documents one
mode of transmission of this pathogen. This inv
tigation also suggests the relative insensitivit
of current methods for identifying persons infec
with this organism, either by the culturing of r
domly selected isolates or by measuring serologi
responses.

5171 THE PATHOGENESIS OF SHIGELLA DIARRHEA. VI. TOXIN AND ANTITOXIN IN Shigella flexneri AND Shigella sonnei INFECTIONS IN HUMANS. (Eng.) Keusch, G. T.; Jacewicz, M. (Mount Sinai Sch. Medicine, New York, NY 10029). *J. Infect. Dis.* 135 (4):552-556; 1977.

Two strains of *Shigella flexneri* (17189 and Sky) and one of *S. sonnei* (18279) were studied for toxin production *in vitro*. HeLa cell cytotoxin was produced by all three strains; this toxin showed marked similarity to that produced by *S. dysenteriae* 1. Each toxin eluted in two distinct peaks on chromatography with Sephadex G-150, was destroyed by heating at 90 C for 30 min, and was neutralized by *S. dysenteriae* 1 antitoxin. Four patients with infections due to *S. flexneri* and *S. sonnei* developed antibody that neutralized *S. dysenteriae* 1 toxin *in vitro*. In three of seven positive sera studied by sucrose density-gradient ultracentrifugation, antibody activity was associated only with the IgM fraction. The time course of the antibody response resembled that found in infections due to *S. dysenteriae* 1, in which an IgM antitoxin antibody has also been described. Since three species of *Shigella* have been shown to be toxigenic, it is possible that bacterial toxin may play a role, along with bacterial invasion, in the pathogenesis of infections due to *S. flexneri* and *S. sonnei*, as well as those due to *S. dysenteriae* 1.

5172 BRIEF COMMUNICATION: THE GARDNER SYNDROME: A FAMILY STUDY IN CELL CULTURE. (Eng.) Danes, B. S.; Krush, A. J. (Lab. Cell Genetics, Dept. Medicine, Cornell Univ. Medical Coll., New York, NY 10021). *J. Natl. Cancer Inst.* 58(3):771-775; 1977.

The *in vitro* detection of increased tetraploidy in skin cultures of epithelial and fibroblast cells was investigated as a method for determining Gardner's syndrome, an autosomal dominant disorder, prior to its clinical manifestation in the intestine. Six families comprising 28 clinically affected individuals, 50 who might carry the gene for the syndrome, and 59 who were not at risk of developing the syndrome were examined. Increased tetraploidy was found to be specific for epithelioid cells and was observed in 9-22% of the cells taken from the 28 affected members. The percentage of cells showing increased tetraploidy was consistent during repeated tests for each individual and was apparently not influenced by age. Increased tetraploidy was also observed in 10-35% of the cells taken from 19/50 members who were at risk of developing the syndrome. No increased tetraploidy (<6%) was found in 56/59 members who were not at risk. The possible nonspecificity of increased tetraploidy for Gardner's syndrome is discussed.

5173 CLINICAL IMMUNITY IN ACUTE GASTROENTERITIS CAUSED BY NORWALK AGENT. (Eng.) Parrino, T. A.; Schreiber, D. S.; Trier, J. S.; Kapikian, A. Z.; Blacklow, N. R. (Univ. Massachusetts Medical Sch., 55 Lake Ave. North, Worcester, MA 01605). *N. Engl. J. Med.* 297(2):86-89; 1977.

To examine immunity in viral gastroenteritis, 12 volunteers were challenged and rechallenged with Norwalk agent; symptoms, jejunal biopsies, and serum antibody were evaluated. With the first challenge, gastroenteritis developed in six volunteers. When rechallenged 27 to 42 months later, these six again had gastroenteritis with jejunal lesions; in the six previously immune volunteers, illness or jejunal lesions did not develop. Four of five ill volunteers had increases in serum antibody to Norwalk agent after both challenges. Serum antibody did not increase in three immune volunteers after either challenge. Four volunteers who had become ill twice underwent a third challenge 4-8 weeks after their second illness. Gastroenteritis developed in one. These findings indicate two forms of immunity for viral gastroenteritis, one of short and the other of long duration. Factors other than serum antibody appear to be important in immunity to Norwalk gastroenteritis.

5174 INTESTINAL IMMUNOCYTES AND IMMUNOGLOBULINS IN PATIENTS WITH PRIMARY HYPOGAMMAGLOBULINEMIA. STUDY OF 26 CASES. (Fre.) Matuchansky, C.; Galian, A.; Goldfain, D.; Rambaud, J. C.; Modigliani, R.; Bernier, J. J. (Hopital Saint-Lazare, F-75010 Paris, France). *Gastroenterol. Clin. Biol.* 1(4): 331-343; 1977.

The number of gut immunocytes was compared with serum Ig levels in 19 patients with primary hypogammaglobulinemia (PH) and 7 patients with selective IgA deficiency (AD). Direct immunofluorescence was used to count IgA, IgG, and IgM immunocytes in the jejunal, colonic, and rectal mucosa, and the IgA levels in the jejunal and salivary fluids were measured. All the patients with AD had no or very few IgA gut immunocytes, while their IgM immunocyte levels were normal or increased. Of the 19 patients with PH, 11 had no recognizable gut immunocytes and nonexistent or very low IgA levels; 6 patients had normal immunocyte numbers in one or more intestinal segments, and 2 with normal serum IgA levels had very few IgA immunocytes in the jejunum. There was no correlation between low numbers of gut immunocytes and the frequency of gastrointestinal abnormalities, except for giardiasis. These findings confirm the dissociation between gut immunocytes and serum immunoglobulin levels and emphasize the need for multiple gut biopsies in PH patients.

5175 GASTRIC EMPTYING AND SECRETION IN ZOLLINGER-ELLISON SYNDROME. (Eng.) Dubois, A.; Van Eerdewegh, P.; Gardner, J. D. (Natl. Naval Medical Center, Bethesda, MD 20014). *J. Clin. Invest.* 59(2):255-263; 1977.

Intragastric volume and rates of gastric emptying and secretion were determined in three patients with Zollinger-Ellison Syndrome (ZES) with and without metiamide administration and in seven normal subjects with and without pentagastrin administration. Gastric hypersecretion was observed both in patients with ZES (9- to 28-fold) and in normal subjects (4- to 18-fold) receiving pentagastrin (5 μg/kg/hr). The fraction of gastric contents emptied per minute (fractional rate of emptying) was three to five times greater in ZES patients (19 ± 6%/min) and was unchanged in normal subjects receiving pentagastrin (6 ± 0.7%/min). The increased fractional rate of gastric emptying in fasting patients with ZES persisted (16 ± 2%/min) despite abolition of gastric hypersecretion by metiamide (4 mg/kg/hr). The administration of metiamide reduced the volume of the intragastric contents to 10 ± 0.4 ml as compared to 24 ± 5 ml of normal fasting subjects and 42 ± 6 ml of ZES patients. After administration of a 250 ml liquid meal, the rate of gastric water secretion increased to the same extent both in normal subjects and in patients with ZES, but in the ZES group, the secretory rate returned to basal values more rapidly than it did in normal subjects. The increased fractional gastric emptying seen in patients with ZES syndrome is not attributable to hypergastrinemia or to gastric hypersecretion but may be caused by an undefined nervous or humoral factor.

5176 LIVER DISEASE IN RENAL TRANSPLANT RECIPIENTS.

(Eng.) Anuras, S.; Piros, J.; Bonney, W. W.; Forker, E. L.; Colville, D. S.; Corry, R. J. (Univ. Hosp., Iowa City, IA 52242). *Arch. Intern. Med.* 137(1):42-48; 1977.

The causes, history, and prognosis of liver disease in patients on renal transplant service were investigated. Fourteen of 156 (8.9%) patients developed significant liver diseases 7 weeks-15 months after renal transplantation. Nine had chronic hepatitis (patients 1-9), 2 had acute cytomegalovirus hepatitis (patients 10 and 11), and one each had fulminant herpes simplex hepatitis (patient 13 died of acute liver failure), granulomatous hepatitis (patient 12), intrahepatic cholestasis (patient 7), and severe fatty metamorphosis (patient 14 died). Patient 7 had prolonged intrahepatic cholestasis and then acute cytomegalovirus hepatitis followed by rejection. Chronic active hepatitis appeared following a second renal transplant. In general, patients 1-9 had few symptoms of liver disease, even though the course of chronic active hepatitis was progressive. Large doses of prednisone and discontinuation of azathioprine or methyldopa had no effect on liver function. Bilirubin increased only slightly (<3 mg/100 ml). Marked elevation of the SGOT value (150-1,650 mU/ml), elevation in the alkaline phosphatase value (195-675 mU/ml), and elevation of the globulin level (3-4.2 g/100 ml) were seen. Hepatitis B surface antigen was persistently positive in three patients (patients 1, 5, and 8). Cirrhosis ultimately developed in five of the nine patients (patients 1, 2, 5, 6, and 9). Patients 1 and 2 died of hepatic failure and patient 6 because of *Pseudomonas septicemia*. All of the remaining survivors had abnormal liver function test results.

5177 ANTRAL GASTRIN CONCENTRATION IN UPPER GASTROINTESTINAL DISEASE.

(Eng.) Hughes, W. S.; Snyder, N.; Hernandez, A. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Dig. Dis.* 22(3):201-208; 1977.

Antral gastrin concentration (AGC) was measured in prepyloric mucosa specimens obtained by forceps biopsy during endoscopic examination of 174 patients. AGC in 32 patients with normal endoscopic findings (controls) varied from 2 to 38.6 ng gastrin/mg tissue. The mean AGC of the control patients was 14.2 ± 1.4 ng gastrin/mg tissue. AGC was similar to control values in 18 patients with duodenal ulcer (14.7 ± 2.1 ng/mg), 12 patients with a pyloric channel or antral ulcer (16.4 ± 3.5 ng/mg), and 48 patients with miscellaneous diagnoses (14.3 ± 1.5 ng/mg). AGC was significantly less than control values in 13 patients with an ulcer in the body or fundus of the stomach (5.9 ± 1.5 ng/mg) and in 4 patients with the Zollinger-Ellison syndrome (4.9 ± 2.4 ng/mg). AGC was significantly greater than in control values in 16 patients with gastritis (25.8 ± 4.3 ng/mg), 22 patients with esophagitis (23.2 ± 3.0 ng/mg), and 9 patients with gastric atrophy and fasting serum hypergastrinemia (44.6 ± 12.3 ng/mg). In 77 of these patients with heterogeneous diagnoses, meal-stimulated 3-hr integrated gastrin output was directly related to AGC ($r=0.47$, $p<0.001$). In a group of 106 patients, AGC was inversely related to histalog-stimulated maximum acid output. The correlation was very weak ($r=-0.20$) but significant ($p<0.05$). The authors conclude that the most likely cause for sample variation in antral gastrin concentration is a combination of three factors: the inherent variability of the gastrin content within the antrum, inadvertent biopsy of tissue outside the antral area, and the presence of patchy disease in the antrum accompanied by irregular loss of G cells.

5178 CELL CONTACTS AND POLYSOMES IN IRRADIATED HUMAN JEJUNAL MUCOSA AT ONSET OF EPITHELIAL REPAIR.

(Eng.) Wartiovaara, J.; Tarpila, S. (Third Dept. Pathology, Univ. Helsinki, Haartmaninkatu 3, 00290 Helsinki 29, Finland). *Lab. Invest.* 36(6):660-665; 1977.

To investigate the early events of jejunal repair, the epithelial ultrastructure was studied in the jejunal biopsies of six patients that had received abdominal irradiation 1-3 days previously. There were major changes in the typical atrophic areas lacking villi. Cell contacts were loose between surface epithelial cells lacking signs of degenerati and extracellular gaps were visible between the lateral membrane interdigitations. Numerous processes from these epithelial cells extended into the underlying basement membrane and sometimes, especially in crypt areas, came into close contact with processes from the underlying mesenchymal cells The epithelial cells often had enlarged nucleoli with granular threads. Increased amounts of epithelial cells were also seen with numerous membrane-free polysomes. The study suggests that at the onset of jejunal epithelial regeneration in man, an epitheliomesenchymal cell interaction takes place similar to that described in normal gut development in laboratory animals. The increase in polysomes is interpreted as a morphologic sign of activated protein synthesis in the differentiating cells of the epithelium.

5179 A STUDY ON THE NATURE OF MACROAMYLASE COMPLEX. DISSOCIATION OF MACROAMYLASE BY SUBSTRATES. (Eng.) Kitamura, T.; Yoshioka, K.; Ehara, M.; Akedo, H. (Center Adult Diseases, Osaka, Higashinari-ku, Osaka 537, Japan). *Gastroenterology* 73(1):46-51; 1977.

Characteristics of a macroamylase from a human subject that was considered not to be formed by the binding of normal amylase to immunoglobulins were studied. The macroamylase was reversibly dissociated into apparently normal amylase by treating the macroamylasemic serum with guanidine hydrochloride. Concanavalin A precipitated a large portion of the macroamylase. When the macroamylase was purified by affinity chromatography using an insoluble starch polymer at neutral pH, a considerable dissociation of the enzyme into apparently normal amylase was observed with the purified preparation. Such dissociation of the macroamylase was demonstrated by briefly incubating the patient's serum with a low molecular weight starch, a substrate of the enzyme. Electrophoresis showed that this dissociated enzyme had essentially the same isozymic pattern as that of normal serum amylase. Reconstitution of the macroamylase occurred when the patient's serum was incubated with the low molecular weight starch for a prolonged period to hydrolyze the starch completely, and when the serum was dialyzed. The amylase-binding substance(s) that is supposed to be involved in the formation of macroamylase was found to be released when the enzyme was adsorbed on the insoluble starch polymer at 0 C. The results suggest that the amylase-binding substance(s) binds to the substrate-binding site of normal amylase to form a macroamylase complex.

5180 LACK OF CORRELATION BETWEEN NITROGEN BALANCE AND SERUM INSULIN LEVELS DURING PROTEIN SPARING WITH AND WITHOUT DEXTROSE. (Eng.) Freeman, J. B.; Stegink, L. D.; Wittine, M. F.; Danney, M. M.; Thompson, R. G. (Univ. Hosp., Iowa City, IA 52242). *Gastroenterology* 73(1):31-36; 1977.

The hypothesis that the decreased insulin levels observed during protein sparing therapy are the major factor accounting for the favorable nitrogen balance seen in surgical patients receiving amino acid infusions was tested. Eight morbidly obese patients received amino acid infusions, with and without added dextrose, for sequential 4-day study periods after major abdominal surgery, in a crossover design. Daily infusion of 3 l of 5% amino acids increased lipolysis compared to a dextrose control period. This was evidenced by a small rise in free fatty acid levels from 0.76 ± 0.10 to 0.85 ± 0.05 mM and a rise in ketone body levels from 0.15 ± 0.02 to 0.44 ± 0.04 mM ($p<0.01$). Serum insulin levels fell from 33.3 ± 5.9 to 22.3 ± 2.6 μU/ml, and nitrogen balance improved from -12.3 ± 4.7 to -1.3 ± 1.8 g/day ($p<0.001$). The addition of 50 g of dextrose to each liter of amino acid solution resulted in the return of insulin, free fatty acid, and ketone body levels to values noted during the dextrose infusion period, but did not affect nitrogen balance. The order of the amino acid and the amino acid plus dextrose infusion periods did not affect the results. Glucagon and growth hormone levels did not differ significantly between study periods. The improved nitrogen balance noted during peripheral amino acid infusion is not attributable to insulin changes alone, but is related both to the availability of an adequate exogenous supply of essential amino acids, and the ability of the body to mobilize endogenous lipid supplies.

5181 ZOLLINGER-ELLISON SYNDROME AND PARATHYROID ADENOMA. LIMITS OF WERMER'S SYNDROME. (Fre.) Champault, G.; Chapuis, Y.; Patel, J. C.; Louvel, A.; Ghozlan, R.; Cachin, M.; *et al.* (Hopital Cochin, Paris, France). *J. Chir. (Paris)* 112(3):131-144; 1976.

Parasitology

5239 CELLULAR SENSITIVITY IN AMOEBIASIS--PRELIMINARY RESULTS OF LYMPHOCYTIC TRANSFORMATION IN RESPONSE TO SPECIFIC ANTIGEN AND TO MITOGEN IN CARRIER AND DISEASE STATES. (Eng.) Harris, W. G.; Bray, R. S. (Medical Res. Council Lab., P.O. Box 273, Banjul, Gambia). *Trans. R. Soc. Trop. Med. Hyg.* 70(4):340-343; 1976.

The cellular sensitivity to *Entamoeba histolytica* was determined in unexposed subjects, asymptomatic amebiasis carriers, patients with clinical amebiasis, and patients with amebic liver abscesses. Specific anti-amebic IgM and IgG were measured by a fluorescent antibody method. Lymphocyte cultures were stimulated with amebic antigen at a final culture concentration of 1 μg and 10 μg/ml protein. The six unexposed subjects without amebiasis showed no evidence of immunological sensitivity; antibody titers were not significant and no lymphocyte transformation was stimulated by amebic antigen. The 10 asymptomatic carriers (i.e., passing cysts in the stools) had slightly elevated specific anti-amebic IgM (10-40) and IgG (20-160), but did not show significant transformation to amebic antigen. Cells from these patients responded normally to phytohemagglutinin, purified protein derivative of tuberculin, and malaria antigen. Cells from the nine patients with clinical amebic dysentery and from the six patients with liver abscess showed significant transformation, and this was more marked in the cells from the patients with liver abscess. Antibody levels among the two patient groups were higher than those in the first two groups, and were particularly high among the patients with liver abscesses (20-32 for IgM; 160-1,000 for IgG). Primary invasion of amebae into the bowel (at clinical or subclinical level) may be associated with a degree of specific cellular immunodepression, which operates on the afferent pathway rather than by inhibiting or destroying effector cells, as no central sensitization can be detected.

5240 INVASIVE AMEBIASIS. I. AMEBIC DYSENTERY AND ITS COMPLICATIONS. (Eng.) Adams, E. B.; MacLeod, I. N. (Dept. Medicine, Univ. Natal, Durban, South Africa). *Medicine* 56(4):315-323; 1977.

The records of 5,087 patients with invasive amebiasis admitted to one medical unit over a 20-yr period were examined to determine the efficacy of treatment in uncomplicated cases and the dangers of complications. Intestinal amebiasis was present in 3,013 cases. Excellent results followed treatment of uncomplicated dysentery (2,854 cases) with various drug combinations or with metronidazole alone and maintenance of fluid balance (fatality rate, 0.5%). Peritonitis was the most common and dangerous complication (fatality rate, 40.2%). Slow leakage over a wide area of bowel rather than acute rupture from one site was the usual type encountered. Since surgery is hazardous in these patients because of the friable state of the bowel, treatment consists of amebicides, antibiotics, and the maintenance of fluid and electrolyte balance. The high death rate is part[illegible] to many patients being admitted late in the course of the disease, i.e., with established peritoni[illegible]. The prognosis is much better in those who develop slow onset-type peritonitis in the hospital. [illegible] common and less dangerous complications are [illegible]ture formation, ameboma, and ulcerative pos[illegible]enteric colitis.

5241 INVASIVE AMEBIASIS. II. AMEBIC LIVER ABSCESS AND ITS COMPLICATIONS. ([illegible] Adams, E. B.; MacLeod, I. N. (Dept. Medicine, [illegible] Natal, Durban, South Africa). *Medicine* 56(4):[illegible]334; 1977.

The records of 2,074 patients with hepatic amebiasis admitted to one medical unit over a 20-yr period were analyzed to determine the efficacy of tre[illegible]ment with tissue amebicides and aspiration of the abscess and, also, the dangers of some of the complications. When the abscess remained confined to the liver, the fatality rate was low (0.7%). Metronidazole combined with aspiration appears to be the treatment of choice. In contrast, w[illegible] there was extension into the pericardium, the fatality rate was high (29.6%). Amebic pericarditis presents in three ways: as pericarditis complicating a known case of amebic liver abscess, [illegible] cardiac failure of obscure etiology, and i[illegible] from rapid cardiac tamponade. The latter two varieties are readily missed. When the pleura[illegible] lungs are involved, the prognosis is relatively good (fatality rate, 6.2%), probably because hepatobronchial fistula being common, amebic pus is often coughed up, providing spontaneous dra[illegible] and pleural effusions are readily diagnosed [illegible] aspirated. Peritonitis arising from the ruptur[illegible] a liver abscess carries a better prognosis than [illegible] intestinal variety. Here the treatment of choic[illegible] surgical drainage, since friable bowel wall does not complicate the procedure.

5242 MECHANISM OF MALABSORPTION IN GIARDIASIS: A STUDY OF BACTERIAL FLORA AND BILE SALT DECONJUGATION IN UPPER JEJUNUM. (Eng.) Tandon, B. N.; Tandon, R. K.; Satpathy, B. K.; Shriniwas (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India). *Gut* 18(3):176-181; 1977.

Because bacterial overgrowth is associated with bile salt deconjugation in some situations, the bacterial content and bile acid profile were determined in intestinal aspirates of patients with giardiasis and steatorrhea. Sixty-three unselected patients with giardiasis, with no evidence of other systemic disease, were scre[illegible] for evidence of steatorrhea. No patient had any evidence of protein-energy malnutrition. Seventeen of the patients had steatorrhea, 3 of whom also had D-xylose malabsorption. Vitamin B_{12} absorption was normal in all. Bacterial culture and qual[illegible] analysis of bile salt in jejunal fluid were carried out in the 17 patients and in 13 additional patients with normal absorptive parameters (8 cases of irritable bowel syndrome and 5 cases of *Giardia* infection), who served as controls. Significant bacterial overgrowth was noted in 8/17 cases and in none of the controls. All patients showing bacterial overgrowth had free bile acids in their duodenal aspirate. Free bile acids were also detected in jejunal aspirates of five of seven patients without bacterial overgrowth. Two control cases of *Giardia* infection with normal small bowel function and sterile duodenal aspirate showed evidence of bile salt deconjugation. The results suggest that bacterial overgrowth and bile salt deconjugation are involved in the pathogenesis of fat malabsorption in giardiasis.

5243 HYDATID DISEASE IN NEW ZEALAND: CHANGING PATTERNS IN HUMAN INFECTION, 1878-1972.

(Eng.) Burridge, M. J.; Schwabe, C. W.; Fraser, J. (Coll. Veterinary Medicine, Box J-125, JHMHC, Univ. Florida, Gainesville, FL 32610). *N.Z. Med. J.* 583(85):173-177; 1976.

Temporal trends in the prevalence and incidence of human hydatid disease in New Zealand were studied with respect to the different phases in echinococcal control. The prevalence rate increased steadily from 1878 to 1954. There were 1,342 new cases of hydatid disease diagnosed in public hospitals between 1951 and 1972. The incidence rate was more than six times as high for Maoris as for non-Maoris and slightly higher for men than for women. The age-specific incidence rates declined most rapidly in children, especially in the 0-4 yr age group, during 1961-1970. There was little difference in the temporal trend in incidence by sex. There was a continuous decrease in the incidence rate of hydatid disease from 1951 to 1972 for non-Maoris, but no marked reduction was seen in Maoris until after 1960. The most common sites of hydatid cysts in the 1,290 new cases diagnosed between 1951 and 1970 were the liver of 47.3% of the patients, the lung in 30.8%, and in the abdomen (excluding the liver) of 18.4%. This study shows that although a decrease in the incidence of human hydatid disease started in the early 1950's, marked reduction in incidence in young children and in Maoris was not evident until after the intensification of control activities in 1957.

5244 PRIMARY PERFORATED PANCREATIC HYDATIDOSIS.

(Spa.) Miguel Velasco, J. E.; Dominguez Sayans, J.; Suarez San Pedro, F.; Parada Herrero, R.; Soleto Saez, E.; Landa, I. (Ciudad Sanitaria de la Seguridad Social "La Paz," Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(6):771-784; 1976.

Primary perforated pancreatic hydatid disease is an extremely rare disorder that occurs principally in Mediterranean and South American countries and Australia. In the case presented, a 12-yr-old boy had undergone splenectomy for ruptured spleen due to trauma. During the operation, no sign of hydatid disease was noted. Two months later, the child presented with abdominal pain, and radiography revealed marked displacement of stomach and liver. During the examination period, the child developed acute abdomen and underwent emergency laparotomy. A hydatid cyst, which contained 4 l of fluid, was drained and removed from the head of the pancreas. No other sites of hydatid disease were discovered; the child recovered and showed no further indications of the disease. In reviewing the literature, the authors discuss the etiopathology, symptomology, diagnosis, prognosis, possible complications, and treatment for pancreatic hydatid disease.

5245 MORBIDITY FROM Schistosoma mansoni INFECTIONS: AN EPIDEMIOLOGIC STUDY BASED ON QUANTITATIVE ANALYSIS OF EGG EXCRETION IN ETHIOPIAN CHILDREN.

(Eng.) Hiatt, R. A.; Gebre-Medhin, M. (Sch. Public Health, Univ. California, Berkeley, CA 94720). *Am. J. Trop. Med. Hyg.* 26(3):473-481; 1977.

Morbidity from infection with *Schistosoma mansoni* was investigated in a population of school childre aged 7-16 yr, from a town in Ethiopia. Malaria was under control in the area, and *S. haemotobium* was not endemic. Quantitative fecal egg counts were determined for 336 children (94% of those in the school) by a thick-smear method; other intestinal parasites were determined by a formol-ether concentration method. Morbidity was measured by a standardized medical examination of 272 of these children and was analyzed in four categories of egg count intensity: 0 (12%), 1-100 (19%), 101-500 (40%), and >501 (29%) eggs per gram (epg). Prevalence was 88%, and the geometric mean egg count was 259 epg. The highest prevalence and intensity were found in 12-yr-olds (95% and 300 egp, resp.). No schistosomiasis-associated symptoms were significantly related to the intensity of *S. mansoni* infection, although blood in the stool was more frequent in groups with higher egg counts. There was a trend for hepatomegaly (especially of the left lobe) to increase in frequency with increasin egg count, but this trend was not significant. No splenic enlargement was present. Anthropometric weight-for-height measurements, average school grade, and days absent from school were not related to the intensity of *S. mansoni* infections. Physical performance was better in uninfected boys but there was no correlation with the intensity of infection. The minimal morbidity is compatible with the moderately low intensity of *S. mansoni* infection and with the findings of a previous population-based study in a neighboring village.

5246 CAUSES OF WEIGHT LOSS ASSOCIATED WITH ENTERIC PARASITISM [Abstract].

GENERAL

Regional Enteritis

5253 EARLY CANCER IN A SEGMENTAL COLITIS WITH LOCALIZED POLYPOSIS. (Spa.) Coronado Quesada, E. F.; Vaccarezza, C. M.; Mounier, C. A.; Loyato, H.; Rapaport, M.; Rubio, H. H. (Unidad de Gastroenterologia, Hosp. J. A. Fernandez, Buenos Aires, Argentina). *Arq. Gastroenterol.* 14(2):89-92; 1977.

A radiological and colonoscopic diagnosis of chronic "segmental" colitis, Crohn's disease, accompanied a histologic diagnosis of early intramucosal adenocarcinoma in a 66-yr-old man who presented with recurrent mucous diarrhea. The patient recovered satisfactorily after left hemicolectomy with a transverse sigmoidal anastomosis. Macroscopic and microscopic examination of the excised colonic segment revealed multiple polypoid adenomas with inflammatory polyps, diffuse glandular atrophy, a coarsened submucosa, and sympathetic cell hypertrophy. No microabscesses, histological fissures, fistulas, or granulomas were found.

5254 RECTAL BIOPSY AS A PROGNOSTIC GUIDE IN CROHN'S COLITIS. (Eng.) Ward, M.; Webb, J. N. (Western General Hosp., Edinburgh, Scotland). *J. Clin. Pathol.* 30(2):126-131; 1977.

The usefulness of rectal biopsy as an indicator of prognosis in Crohn's proctocolitis was assessed in 27 patients. The clinical course following biopsy was assessed, and the patients were included in one of four categories: (1) those remaining asymptomatic, (2) those showing continued moderate inflammatory activity, (3) those requiring colectomy, and (4) those dying as a direct result of colonic disease. The use of student's *t* test applied to first rectal biopsies showed a significant difference between scores of the death group and the moderate group ($p<0.05$) and between the death group and the asymptomatic group ($p<0.05$). In no biopsy (either first biopsy or subsequent biopsies) from patients in groups 1 and 2 was a fissure found, whereas these were present in between 30% and 50% of the biopsies in groups 3 and 4. Ulceration also suggested a poor prognosis. The results suggest that there are features to be found in the rectal biopsies of patients with Crohn's colitis that give some indication of the ultimate prognosis, and that biopsy appearances are relatively constant.

5255 FURTHER ELECTRON MICROSCOPIC EVIDENCE OF VIRUS-LIKE PARTICLES IN CROHN'S DISEASE. (Eng.) Riemann, J. F. (Medizinische Universitatsklinik, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 24(2):116-118; 1977.

Biopsy specimens from nine patients with Crohn's disease of the colon were studied ultrastructurally to identify and localize virus-like particles. In the biopsy specimens of the descending colon of seven patients, virus-like particles were encountere mainly in the epithelial cells and macrophages near ulcerative lesions. These particles had a double membrane and a sometimes electron-opaque central core. They were round to oval in shape, and their diameter was 30-70 nm. They were commonly located in clusters, but were also found singly in the cell cytoplasm. These observations support the suggestion that Crohn's disease is associated with a transmissible viral agent.

5256 MEDICAL MANAGEMENT OF CROHN'S DISEASE IN ADOLESCENCE. (Eng.) Whittington, P. F.;

Barnes, H. V.; Bayless, T. M. (Univ. Wisconsin Sch. Medicine, Madison, WI). *Gastroenterology* 72(6):1338-1344; 1977.

An attempt was undertaken to suppress the disease process throughout adolescence without unwanted drug side-effects in 16 adolescent patients with Crohn's disease. Fourteen patients received long-term prednisone therapy (initial mean dose, 1.05 mg/kg/day; after 6 months, 0.35 mg/kg/day) along with either salicylazosulfapyridine (dose range, 1.5-3.0 mg/kg/day) or tetracycline (dose range, 10.8-37.9 mg/kg/day) for 3.5 years. Two patients did not receive long-term prednisone therapy; they remained asymptomatic on tetracycline or salicylazosulfapyridine. By 1 yr after the beginning of therapy, 13/16 patients were asymptomatic, and only 1/16 required hospitalization for symptoms during the 3.5-yr follow-up period; the one patient rehospitalized underwent bowel surgery. Alternate day corticosteroid administration was attained in 11 patients. Ten of these patients were reported to be growing and developing at a normal rate. Total weight gain averaged 17.5 kg and height 152.4 cm in all 14 patients. Thirteen of 16 patients achieved pubertal development appropriate for the age. Eight patients with distal ileal disease gave excellent response to medical therapy; those with more extensive disease were difficult to manage. No major adverse effects from the drug therapy were reported to interfere with patients' regular activities. It is concluded that an effort to suppress disease activity continuously in adolescents with Crohn's disease is needed to correct the disease-related growth-rate suppression.

5257 ILEORECTAL ANASTOMOSIS IN PATIENTS WITH CROHN'S DISEASE OF THE COLON. (Eng.)

Flint, G.; Strauss, R.; Platt, N.; Wise, L. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Gut* 18(3):236-239; 1977.

Thirty-seven patients who had an ileorectal anastomosis performed for Crohn's disease of the colon were studied and compared with patients who had a total colectomy and ileostomy for the same disease. Twenty-nine operations were done as a primary procedure, and in eight the anastomosis was made after previous total or segmental colectomy. Three patients developed anastomotic leaks and died. No patient who had a diverting loop ileostomy performed at the time of ileorectal anastomosis developed anastomotic leaks before or after the ileostomy was closed. Of the 37 patients, 3 died postoperatively and another 5 have had less than a 1-yr follow-up. Of the remaining 29 patients, 12 had recurrences in either the rectum or ileum. Half of the recurrences took place 5 yr or more after surgery. Seven of the 12 patients with recurrences have had their anastomoses taken down. When this recurrence rate of 41% is compared with the recurrence of ileitis in patients after total colectomy and ileostomy for Crohn's disease of the colon, the incidence of recurrence is not markedly dissimilar. Of the patients who develop a recurrence after ileorectal anastomosis, only about half will have to have their anastomoses taken down. In this study, 59% of the patients had no recurrence and another 20.5% had a recurrence but the anastomosis did not have to be taken down. Thus, almost 80% of the patients have been able to lead a life unencumbered by an ileostomy, making ileorectal anastomosi
for this disease desirable in selected patients.

5258 CROHN'S DISEASE IN BLACK PATIENTS. (Eng.

Mosley, E., Jr.; Rogers, N.; Scott, V.; Chung, E. B.; Press, H. C., Jr.; Leffall, L. D., J
(Howard Univ. Hosp., Washington, DC 20060). *J. Na*
Med. Assoc. 69(4):219-222; 1977.

Experience with Crohn's disease at one hospital during a 10-yr period is reviewed, and differences in manifestation of the disease in a predominantly black population are noted. There were 13 patient
(10 women) with a diagnosis of Crohn's disease (transmural colitis, transmural enteritis, granulomatous colitis, granulomatous enteritis, ileocolit
and regional enteritis or colitis). The most comm
presenting symptoms were right lower quadrant pain (76.7%), diarrhea (69.2%), anorexia (69.2%), weigh
loss (53.8%), and vomiting (53.8%). The most comm
physical finding was right lower quadrant tenderne
(76.7%). The patients were grouped according to the site of involvement: ileocolic (9 patients), small bowel only (3 patients), and large bowel onl
(1 patient). Eight patients had surgical resectio
six of whom had ileocolic involvement. The most commonly performed operation was ileocolic resecti
with ileo-ascending colostomy (75%). The chief indication for surgery was acute abdomen (62%); two of these patients had a preoperative diagnosis of intestinal obstruction, and three had a preoper
tive diagnosis of appendicitis. Intestinal fistul
was diagnosed in two patients and tubo-ovarian abscess in one. When this series was compared to previously reported series of white patients, ther
were more females and more ileocolic involvement among the predominantly black population. In most other series, the greatest involvement occurred in the ileum alone. Crohn's disease seems to occur in blacks much less frequently than in whites.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism a Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal trac Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The numbe and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone	ml, µl	milli-, microliter(s)
ADP	adenosine diphosphate	mm	millimeter(s)
AMP	adenosine monophosphate	mOsm	milliosmolar; milliosmeter(s)
amp	ampere	msec	millisecond(s)
ATP	adenosine triphosphate	mV	millivolt(s)
A	angstrom	min	minute(s)
BSP	sulfobromophthalein	MTD	maximum tolerated dose
C	degrees centigrade	NAD	nicotinamide adenine dinucleotide
cal	calories	NADH	reduced nicotinamide adenine dinucleotide
cc	cubic centimeter	NADP	nicotinamide adenine dinucleotidephosphate
cm	centimeter(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
dl	deciliter	ng	nanogram (10^{-9})
DNA	deoxyribonucleic acid	nm	nanometer(s)
ED_{50}	median effective dose(s)	Pa	ambient pressure
EDTA	ethylenediamine tetraacetic acid	PAS	periodic acid - Schiff
e.g.	for example	pg	picogram (10^{-12})
EEG	electroencephalogram	pgEq	picogram equivalent(s)
ESR	erythrocyte sedimentation rate	p.o.	orally
g	gram(s)	ppb	parts per billion
µg	microgram(s)	ppm	parts per million
Hz	Hertz	r	Roentgen
hr	hour(s)	RBC	red blood cells (erythrocytes), red blood count
Ig	immunoglobulin(s)	resp.	respectively
i.m.	intramuscular	RNA	ribonucleic acid
i.p.	intraperitoneal	s.c.	subcutaneous
IU	international unit(s)	sec	second(s)
i.v.	intravenous	SGOT	serum glutamic-oxalacetic transaminase
kcal	kilocalorie(s)	SGPT	serum glutamic-pyruvic transaminase
kg	kilogram(s)	U	unit(s)
K_m	Michaelis constant	UV	ultraviolet
LD_{50}	median lethal dose(s)	V	volt
LDH	lactic acid dehydrogenase	WBC	white blood cells (leukocytes), white blood count
m	meter(s)	yr	year(s)
M	molar; mole(s)		
mM	millimolar; millimole(s)		
µM	micromolar; micromole(s)		
ma	milliampere(s)		
mCi, µCi	milli-, microcurie(s)		
mEq	milliequivalent(s)		
mg	milligram(s)

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

261 A STUDY OF THE PROTEINS OF THE BRUSH BORDER OF CANINE ENTEROCYTES. (Fre.) Star- ta-Geribaldi, M.; Fehlmann, M.; Sudaka, P. (Faculte e Medecine, Universite de Nice, Chemin de Vallom- rose, F-06200, Nice, France). *Arch. Int. Physiol. iochim.* 85(2):245-254; 1977.

roteins of the brush borders of canine enterocytes ere examined by gel electrophoresis. Microvilli ere isolated from the dog jejunal and ileal entero- ytes by successive homogenization and ultracentrifu- ation. A final yield of 22% was obtained, and the urified fraction showed a 19-fold increase in sucrase ctivity over the starting material. After solu- ilization with 2% sodium dodecylsulphate, the roteins were analyzed by polyacrilamide gel elec- rophoresis. After electrophoretic separation, 21 rotein bands were obtained, with molecular weights anging from 15,000 to over 340,000. Most of the roteins had molecular weights over 70,000. Glyco- roteins were found in seven bands, with molecular eights of 150,000 to over 340,000. Identical ands were obtained from jejunal and ileal prepa- ations.

262 ELECTRON MICROSCOPIC STUDIES ON ENDOCRINE CELLS AND EXOCRINE CELLS IN GASTRIC MUCOSA F RATS. I. ENDOCRINE CELLS IN GASTRIC MUCOSA OF ASTING RATS. (Jpn.) Sano, M. (2nd Surgical Dept., yoto Univ., Kyoto, Japan). *Arch. Jpn. Chir.* 45(4): 43-264; 1976.

asal granulated (endocrine) cells in the gastric ucosa of rats were examined by light and electron icroscopy after a 48-hr fast. Oval or pyramidal lear cells containing cytoplasmic granules were asily distinguished from other epithelial cells sing toluidine blue stain. These cells appeared ainly in the deeper two-thirds of the pyloric gland nd in the basal area of the fundic gland. Electron icroscopy revealed a well-developed Golgi apparatus, ree ribosomes, rough endoplasmic reticulum, mito- hondria, centrioles, microfilaments, and character- stic secretory granules. Most endocrine cells of he pyloric gland were on the surface of the lumen f the gland with specific microvilli at their pexes, suggesting that these cells receive chemical timuli from the lumen. In the fundic gland, the ells were located near nerve endings, suggesting hat the fundic endocrine cells are regulated by ervous stimulation. The cells were classified ccording to their fine structures: types G, EC, , D_1, and IV in the pyloric glands, and ECL and in the fundic glands. G cells were the most numerous ells in the pyloric glands. The secretory granules 50-300 μm in diameter. The electron density of he G cell granules was usually low. EC cells ontained polymorphous secretory granules, which ere about 200 μm in diameter and of high electron ensity. The basal area of the D cells contained ound granules, about 150-200 μm in diameter. D_1 ells also contained round secretory cells, which were highly electron-dense. These cells contained well-developed microfilaments near the nucleus. IV cells contained a few cored-vesicular granules, about 250-500 μm in diameter. ECL cells were the predominant fundic endocrine cells, and they contained large (300-500 μm) granules of low electron density. A cells contained highly electron dense, round secretory granules (200-250 μm). It is concluded that the endocrine cells observed produce gastrointestinal hormones.

5263 ELECTRON MICROSCOPIC STUDIES ON ENDOCRINE CELLS AND EXOCRINE CELLS IN GASTRIC MUCOSA OF RATS. II. MORPHOLOGICAL CHANGES IN CHIEF CELLS AND PARIETAL CELLS AFTER FASTING, REFEEDING, AND ELECTRICAL VAGAL STIMULATION. (Jpn.) Sano, M. (Shizuoka City Hosp., 10-93, Otemachi, Shizuoka City, Japan). *Arch. Jpn. Chir.* 45(4):265-278; 1976.

The fine structural changes in the chief cells and parietal cells of the rat fundic mucosa were examined after fasting, refeeding, and electrical vagal stimulation. After fasting and subsequent refeeding, the number of zymogen granules in the chief cells decreased, the arrangement of rough endoplasmic reticulum became irregular, the Golgi apparatus enlarged, and progranules were observed near the enlarged Golgi apparatus. These results suggest that both secretion and synthesis of the zymogen granules in the chief cells are stimulated by refeeding. In the parietal cells, the microvilli of the cell surface and the intracellular canaliculi were increased and elongated, and the intracellular canalicular spaces were distended after refeeding. This result suggests that the plasmalemma of the parietal cell is related to the site of secretion and synthesis of HCl. Vacuole-like secretory granules and dilated irregular rough endoplasmic reticulum and Golgi apparatus were observed in the chief cells after electrical vagus stimulation. Increased and elongated microvilli in the distended intracellular canaliculi were observed in the parietal cells after electrical stimulation. The changes seen in both cell types following electrical stimulation were somewhat different from those seen after refeeding. The results suggest that electrical vagus stimulation damages the physiologic cycle of secretion and synthesis of zymogen granules in the chief cells and, possibly, of HCl in the parietal cells.

5264 THE ISOLATION AND CHARACTERIZATION OF A BILE DUCTULE CELL POPULATION FROM NORMAL AND BILE-DUCT LIGATED RAT LIVERS. (Eng.) Grant, A. G.; Billing, B. H. (St. George's Hosp. Medical Sch., Tooting, London, SW17 0QT, England). *Br. J. Exp. Pathol.* 58(3):301-310; 1977.

Bile ductule cells were partially separated from Kupffer and sinusoidal endothelial cells in a suspension of nonparenchymal cells. Bile duct ligation was performed so that a fourfold increase in the total number of nonparenchymal cells isolated from rat liver was attained and the proportions of both Kupffer and bile ductule cells were elevated. Rate zonal centrifugation through a Ficoll gradient partially separated the cells into two populations: small cells (4-6 μm in diameter), probably originating from the sinusoidal endothelium, and larger bile ductule and Kupffer cells (8-12 μm diameter). A more successful separation was achieved by isopycnic centrifugation through a linear metrizamide gradient. Bile duct ligation (14 days) altered the distribution of cells on the gradient, and the peak containing bile ductule and Kupffer cells partially subdivided into the separate cell types. Antiserum raised against the bile ductule fraction was shown to be compatible with that raised against common bile duct tissue. γ-Glutamyl transpeptidase and leucine aminopeptidase activity were preferentially located in the rate zonal fraction containing bile ductule cells. Their specific activity increased after bile duct ligation, as did that of β-glucuronidase, which was raised in all cells. This study shows that the number of bile ductule cells in the liver can be increased by bile duct obstruction, so that their isolation from other cell types becomes possible.

5265 ON MICROSTRUCTURES OF HUMAN PIGMENT GALLSTONES. (Eng.) Wosiewitz, U. (Institut fur Medizinische Physik der Universitat, D-4400 Munster, W. Germany). *Naturwissenschaften* 64(7):390-391; 1977.

The scanning electron microscope was used to study the structure of human pigment gallstones. Black pigment stones from the gallbladder appeared as compact, fine-grained, tarlike masses. The fracture surface of this material gave the appearance of stratification, although this is not the case. "Pure" pigment stones, obtained mainly from the bile ducts, had a different microstructure. These had a porous, spongy texture and were laminated.

5266 MAMMALIAN PANCREAS DEVELOPMENT: REGENERATION AND DIFFERENTIATION IN VITRO. (Eng.) Richardson, K. E. Y.; Spooner, B. S. (Div. Biology, Kansas State Univ., Manhattan, KS 66506). *Dev. Biol.* 58(2):402-420; 1977.

To investigate further the protodifferentiated state of mammalian pancreas development, the primitive guts from 9-day mouse embryos were cultured for 3 days, during which protodifferentiated dorsal pancreas formed, consisting of a neck region or duct that extended from the intestinal wall and terminated in a large bulb of tissue. The pancreas bulb was then removed, leaving only the duct. This day corresponded to day 12 of gestation. During 5 days of additional culture, 37 of 43 ducts regenerated a pancreas with an amylase specific activity equal to that of control pancreas (2.4 μg of maltose hydrate released/min/μg of protein at 37 C. Guts placed in culture at 12 days, with removal of the pancreas the same day, gave similar results. Other combinations of starting embryonic age plus culture time, prior to pancreas removal, totaling 12 or 13 days, also underwent regeneration. Only 1 of 18 pancreases regenerated from ducts equivalent to 14 days of gestation. Removal of the stomach, the intestine, and the ventral pancreas did not affect the ability of the dorsal pancreas to regenerate. However, removal of the duct at the presumptive intestinal wall did not result in regeneration. Regenerated pancreas differentiation was further confirmed by electron microscopic demonstration of zymogen granules in exocrine cells and of at least two types of secretory granules in endocrine cells. The results demonstrate that the protodifferentiated duct can regenerate a new pancreas, including both exocrine and endocrine tissue, and that the regenerated pancreas is not retarded in its development when compared with the control pancreas.

5267 IMMUNOHISTOCHEMICAL DIFFERENTIATION OF THE GLANDS IN THE GASTROESOPHAGEAL (G-E) REGION OF MAN [Abstract]. (Eng.) Weinstein, W. M.; Lechago, J.; Samloff, I. M.; Bowes, K. L. (UCLA Sch. Medicine, Los Angeles, CA). *Gastroenterology* 72(5, Part 2):1147; 1977.

ABSORPTION - EXCRETION - TRANSPORT

5275 PERMEABILITY OF THE RABBIT COLON IN VITRO. (Eng.) Yorio, T.; Bentley, P. J. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Am. J. Physiol.* 232(1):F5-F9; 1977.

The use of rabbit descending colon in *in vitro* permeability studies was assessed, and the permeability properties of this tissue are described. *In vitro* everted sac or diaphragm preparations of New Zealand rabbit descending colons exhibited a transmural potential difference (PD) as high as 70 mV, a short-circuit current (SCC) of 100-150 μamp/cm^2, and a resistance of 300-500 ohms/cm^2. The descending colon maintained these functions for at least 3 hr. Amiloride (10^{-5} M) on the mucosal side of the colon abolished the PD and SCC in everted sac preparations; however, the SCC was restored when the drug was washed from tissue. At a concentration of 10^{-4} M, the effect of amiloride was not reversible. Amphotericin B (12.5 μg/ml) on the mucosal side of the colon stimulated the SCC, but had no significant effect on the PD. Measurements of the influx (mucosa to serosa) and efflux of sodium, chloride, and potassium across the colon (diaphragm preparations) under short-circuit conditions showed a net influx of sodium (3.3 μEq/cm^2/hr) and a net efflux of potassium (-0.34 μEq/cm^2/hr). The SCC could be accounted for by the movements of these ions. The SCC in the presence of 12.5 μg/ml amphotericin B on the mucosal side of the colon (118 microamp/cm^2) was nearly equivalent to the net sodium flux expressed as microamp/cm^2 (110). Amiloride (10^{-4} M) on the mucosal side of the colon abolished the net sodium transfer, but did not have a significant effect on the net flux of potassium. The permeability coefficient for water was 5,147 ± 688 cm/sec, while the permeability coefficient for urea was 26 ± 4.9 cm/sec. The restricted permeability of the rabbit colon to urea, which is much less than in its gallbladder (890 cm/sec), may reflect the excretory role of the colon. The rabbit's colon thus exhibits a diverse permeability to different molecules, and this appears to be consistent with its physiological functions.

5276 MEASUREMENTS OF INTESTINAL PERMEABILITY USING LOW MOLECULAR WEIGHT POLYETHYLENE GLYCOLS (PEG 400): I. CHEMICAL ANALYSIS AND BIOLOGICAL PROPERTIES OF PEG 400. (Eng.) Chadwick, V. S.; Phillips, S. F.; Hofmann, A. F. (Royal Postgraduate Medical Sch., London W12, England). *Gastroenterology* 73(2):241-246; 1977.

The use of a polyethylene glycol complex with an average molecular weight of 400 (PEG 400) for the measurement of intestinal permeability in man is discussed. PEG 400 contains at least nine distinct water-soluble polymeric units with molecular weights ranging from 242-594 daltons. The water-soluble molecules of PEG 400 can be readily extracted from biological fluids and analyzed by gas-liquid chromatography. Experiments involving the i.v. administration of PEG 400 to animals and the p.o administration of PEG 400 to humans indicate that PEG 400 is not toxic, is not degraded by intestinal bacteria, is not metabolized after absorption, and is rapidly excreted in the urine. The percentage absorption of each molecular weight component of PEG 400 was assessed by urinary recovery over 6 hr after p.o. administration (10.0 g) to 10 fasting normal control subjects. Percentage absorption was relatively constant for the four smallest molecular species of PEG 400 (molecular weight, 242-374) and thereafter was inversely proportional to molecular size. The relative absorption of the different molecules was dependent on intestinal permeability alone; thus, a comparison of ratios of the absorption of different molecular weights can be used as a reliable index of permeability. Absorption of PEG 400 was not influenced by the taking of a liquid test meal with a PEG 400 dose of 10 g, p.o. Since PEG 400 is relatively inert chemically and is resistant to bacterial degradation, it is particularly suitable for use in man and allows for studies of permeability in bacterially contaminated regions of the intestine. The absence of tissue metabolism and the rapid urinary excretion of PEG 400 after absorption (56.6 ± 5.8% of the dose is excreted over 48 hr in man) allow for the assessment of intestinal absorption on the basis of urinary excretion either after p.o. administration or when PEG 400 is infused through a tube at different levels in the intestine.

5277 MEASUREMENTS OF INTESTINAL PERMEABILITY USING LOW MOLECULAR WEIGHT POLYETHYLENE GLYCOLS (PEG 400): II. APPLICATION TO NORMAL AND ABNORMAL PERMEABILITY STATES IN MAN AND ANIMALS.

(Eng.) Chadwick, V. S.; Phillips, S. F.; Hofmann, A. F. (Royal Postgraduate Medical Sch., London W12, England). *Gastroenterology* 73(2):247-251; 1977.

A low molecular weight polyethylene glycol complex (PEG 400) was used to study the normal and abnormal permeability states in man and animals. Permeability measurements were made after direct infusions of 10 g of PEG 400 via an intestinal tube into the proximal jejunum, ileum, or cecum of normal human subjects. Absorption of the individual molecular weight components of PEG 400, expressed as a percentage of the dose recovered in the urine over 6 hr, was inversely proportional to molecular weight for each region of the intestine. Steady state regional perfusion studies with five normal volunteers were performed, with permeability being measured during net fluid absorption in four subjects and during net secretion (induced with hyperosmolar saline perfusion) in the fifth subject. In spite of the reversed solvent flow, the PEG 400 permeability profile was not significantly different under these two conditions, suggesting that the permeability technique can be used in absorptive or secretory states. In another study with five normal subjects, PEG 400 absorption increased markedly during the perfusion of 5 mM chenodeoxycholate. The effect of 5 mM taurocholate on the function of Heidenhain pouches in four dogs was studied to assess the effect of bile acids on gastric mucosal permeability. Volume secretion into the pouch decreased from 9.98 ± 5.25 ml/hr in the absence of bile acid to 2.98 ± 2.92 ml/hr in the presence of bile acid. Hydrogen ion secretion into the pouch similarly decreased from a pretreatment value of 0.523 ± 0.37 mEq/hr to 0.286 ± 0.35 mEq/hr after taurocholate treatment. The final pH of the perfusate was 1.95 in taurocholate experiments, compared with 1.45 during control periods. This impairment of function of the pouches was associated with a marked increase in mucosal permeability to all of the molecular components of PEG 400. Permeability studies with celiac sprue patients showed that patients responding poorly to treatment showed decreased permeability to p.o. administered PEG 400 (10.0 g) in comparison with normal volunteers. Celiac sprue patients responding to treatment with a more than 5% weight gain showed intermediate permeability profiles compared with poor responders and normal volunteers. These studies illustrate the potential of the permeability measurement technique for studying the function of diseased intestine in man.

5278 DERIVATION OF THE EQUATIONS THAT DESCRIBE THE EFFECTS OF UNSTIRRED WATER LAYERS ON THE KINETIC PARAMETERS OF ACTIVE TRANSPORT PROCESSES IN THE INTESTINE.

(Eng.) Thomson, A. B. R.; Dietschy, J. M. (Dept. Medicine, 9-112 Clinical Science Building, Univ. Alberta, Edmonton, Alberta T6G 2G3, Canada). *J. Theor. Biol.* 64(2):277-294; 1977.

An equation that describes the velocity of active transport in the intestine as a function of the characteristics of both the transport carrier in the membrane of the epithelial cell and the resistance of the overlying unstirred water layer is presented. Using this equation, a series of curves are presented that depict the effect of varying the thickness or surface area of the unstirred water layer, the free diffusion coefficient of the solute, the distribution of active transport sites along the villus, the maximal transport velocity, and the true Km on the kinetics of active transport. These theoretical curves illustrate serious limitations inherent in the interpretation of previously published data dealing with active transport processes in the intestine. For example, experimentally determined Km values for the transport of a given solute commonly vary significantly when measured in different kinds of *in vitro* preparations and are usually many times higher when measured by perfusion techniques *in vivo*. In view of the marked effect of unstirred water layer resistance on Km values, it is very likely that these observed differences primarily reflect differences in unstirred water layer resistance in these different preparations and not the binding characteristics of the membrane carrier. Since none of the equations describing active transport in the presence of significant unstirred layer resistance take the form of a rectangular hyperbole, the appli cation of the Michaelis-Menten equations with the use of reciprocal plots to derive values for Km an the true maximal transport rate (J^m) is not only theoretically incorrect, but also introduces error in the determination of Km and J^m. It is no longe tenable, therefore, to continue to use such reciprocal plots for the analysis of intestinal tran port data.

5279 EPITHELIAL CELL EXTRUSION DURING FLUID TRANSPORT IN CANINE SMALL INTESTINE.

(Eng.) Lee, J. S. (Univ. Minnesota Medical Sch., Minneapolis, MN 55455). *Am. J. Physiol.* 232(4): E408-E414; 1977.

Epithelial cell extrusion during fluid transport i the canine small intestine was studied under both *in vitro* and *in vivo* conditions. Cell extrusion times for villus tips *in vitro* from membranes of dogs with low (183 ± 25 µl/cm^2/hr) and high (485 ± 30 µl/cm^2/hr) fluid absorption rates were always much shorter in the villi with obstruction of lymp flow (43 ± 4 min and 20 ± 6 min, resp.) than in those with free flow of lymph (33 ± 4 and 11 ± 3 min, resp.). In the villi with obstruction of lym flow, the mean lymph pressure of 31 jejunal villi of nine dogs was 4.5 ± 0.3 mm Hg and that of 30 ileal villi was 2.6 ± 0.2 mm Hg. When the lymph pressure in the jejunal and ileal villi was increa to 6.4 ± 0.2 and 12.3 ± 0.5 mm Hg, resp., by the injection of Ringer solution into the central lacteals, fluid leaked out of the villi and a shed ding of epithelium occurred. Vigorous villus spas modic contraction induced by cocaine (5-10 mM) or atropine (10 mM) also caused a shedding of epithelium. *In vivo*, cells always appeared in the lume of the intestine either during fluid absorption o secretion. A copious secretion of fluid, an

ncrease in cell loss, and congestion of blood in
he villi occurred in villi exposed to isotonic
olutions of magnesium sulfate and choline chloride
r as a result of the action of cholera toxin.
he rate of cell loss was highest during fluid
ecretion induced by an elevation of tissue fluid
ressure during such conditions as high venous
ressure or intra-arterial histamine infusion.
fter intra-arterial histamine infusion for 20 min,
luid secretion rate was measured at 12.9 ± 3.5 ml/
0 min and cell loss at 130 ± 62 x 10^6, or 48-fold
f that when luminal fluid was isotonic sodium
hloride (NaCl) solution. In the jejunal segment,
ppreciable fluid secretion was obtained when the
enous pressure was increased to 40 mm Hg. Fluid
ecretion rate was 3.7 ± 0.4 ml/20 min, and cell
oss was 1,100 ± 480 x 10^6, or more than 400-fold
f that with isotonic NaCl solution. It is thus
oncluded that elevated tissue fluid pressure is
nvolved in epithelial cell extrusion during fluid
ransport in the canine small intestine.

280 INTESTINAL ABSORPTION OF α-TOCOPHEROL IN THE UNANESTHETIZED RAT. THE INFLUENCE OF UMINAL CONSTITUENTS ON THE ABSORPTIVE PROCESS.

Eng.) Muralidhara, K. S.; Hollander, D. (Div.
astroenterology, Wayne State Univ. and Harper
osp., Detroit, MI 48201). *J. Lab. Clin. Med.*
0(1):85-91; 1977.

H-α-tocopherol intestinal absorption was studied
n unanesthetized male Sprague-Dawley rats. The
ate of absorption of α-tocopherol was measured at
erfusate concentrations ranging from 4 nM to 500 μM,
ith the infusate consisting of 10 mM of sodium
aurocholate, 2.5 mM oleic acid, and 2.5 mM mono-
lein micellarized in phosphate buffer at pH 7.4.
he rate of α-tocopherol absorption was linear over
he concentration range. Increasing the sodium
aurocholate concentration to 20 mM in an infusate
omposed of phosphate buffer at pH 7.4 and α-toco-
herol (200 μM) significantly ($p<0.05$) increased
he rate of α-tocopherol absorption from 13.3 ± 0.24
mol/min/10 cm intestine (at 10 mM taurocholate)
o 15.6 ± 0.25 nmol/min/10 cm intestine. The addi-
ion of 2.5 mM saturated and unsaturated long-chain
atty acids to an infusate composed of 10 mM tauro-
holate and 200 μM α-tocopherol significantly
p<0.05) decreased the rate of α-tocopherol absorp-
ion. The most marked decrease in absorption of the
itamin occurred after the addition of 2.5 mM of
he polyunsaturated linolenic acid to the infusate,
ith α-tocopherol absorption decreasing from 13.3 ±
.24 nmol/min/10 cm (no fatty acid was added to the
nfusate) to 8.5 ± 0.52 nmol/min/10 cm when lino-
enic acid was added ($p<0.01$). A progressive
nhibition of α-tocopherol absorption was observed
s the concentration of linolenic acid was increased.
aising the perfusate pH from 4.3 to 8.0 (perfusate
omposed of 200 μM α-tocopherol and 10 mM tauro-
holate micellarized in phosphate buffer) resulted
n a progressive decrease in α-tocopherol absorption
rom 26.3 ± 1.56 to 7.2 ± 0.35 nmol/min/10 cm
p<0.01). These experiments indicate that micellar
xpansion with polyunsaturated fatty acids inter-
eres with the absorption of α-tocopherol and may
esult in a deficiency of the vitamin.

5281 AMINO ACID CONCENTRATIONS IN PORTAL VENOUS PLASMA DURING ABSORPTION FROM THE SMALL INTESTINE OF THE GUINEA PIG OF AN AMINO ACID MIXTURE SIMULATING CASEIN AND A PARTIAL ENZYMIC HYDROLYSATE OF CASEIN.

(Eng.) Sleisenger, M. H.; Pelling, D.; Burston, D.; Matthews, D. M. (Dept. Medicine, Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Clin. Sci. Mol. Med.* 52(3):259-267; 1977.

Ion exchange chromatography was used to investigate amino acid concentrations in the portal venous plasma of female Dunkin Hartley guinea pigs at 5-, 10-, 15-, 20-, 30-, 40-, 50-, and 60-min intervals after infusion into the duodenum of equivalent amounts of an amino acid mixture simulating casein or a partial enzymic hydrolysate of casein. The partial hydrolysate of casein was prepared by hydrolysis with papain followed by hydrolysis with pig-kidney peptidases. For some amino acids such as leucine, isoleucine, valine, phenylalanine, and lysine, the curves for portal plasma amino acid concentration versus time were similar after enzyme hydrolysate or amino acid mixture infusion, although they were usually lower for enzyme hydrolysate treatment. With other amino acids, the curves after enzymic hydrolysate infusion were very much lower than the corresponding curves after amino acid mixture infusion, particularly in the cases of serine, glutamine, proline, and glycine. Portal plasma concentrations of glutamine were significantly lower at 20, 30, and 40 min ($p<0.05$) after enzyme hydrolysate treatment, being -4 ± 7, -5 ± 12, and 1 ± 5 μM, resp., compared with values of 4 ± 4, 12 ± 6, and 12 ± 8 μM, resp., after amino acid treatment. The same was true for serine at 20 min ($p<0.02$), 30 min ($p<0.01$), and 40 min ($p<0.01$) after treatment, with the respective values after enzyme hydrolysate treatment being 122 ± 20, 202 ± 34, and 174 ± 43 μM, compared with values of 259 ± 44, 415 ± 43, and 413 ± 60 μM, resp., after amino acid mixture infusion. For glycine and proline, the portal plasma levels at 30 min after treatment were significantly lower after enzyme hydrolysate treatment, being 1 ± 54 ($p<0.05$) and 326 ± 56 μM ($0.1>p>0.05$), resp., compared with values of 215 ± 66 and 529 ± 96 μM, resp., after amino acid mixture treatment. Similar significant differences were noted for methionine at 10 min post-treatment ($p<0.01$) and for histidine at 40 min after treatment ($p<0.05$). The results can be partially explained by the hypothesis that the lower amino acid concentrations in portal plasma after enzymic hydrolysate treatment are the result of entry of amino acids into the portal blood in a peptide form not detectable by the analytical technique employed. The data may also be possibly explained by a more rapid clearance of amino acids from the blood during absorption of the enzymic hydrolysate.

5282 RESPONSES TO ETHANOL IN RAT STOMACH.

(Eng.) Sernka, T. J.; Jackson, A. F. (Louisiana State Univ. Medical Center, Shreveport, LA 71130). *Nutr. Rep. Int.* 14(4):415-421; 1976.

Ethanol absorption and its effect on gastric acid secretion were studied to serve as a base of comparison for other hyperosmotic gastric effects that have been reported in the rat. The stomachs of rats were successively instilled with isosmotic ethanol solution (1.63%, v/v; 277 ± 4 mOsmol/kg), threefold hyperosmotic ethanol solution (5.24%, v/v; 922 ± 9 mOsmol/kg), and sixfold hyperosmotic ethanol solution (10.5%, v/v; 1,940 ± 7 mOsmol/kg). A rapid rate of ethanol absorption that was linearly related to the instilled concentration was seen. The fraction of ethanol absorbed per half-hour was 28% from 1.63% ethanol; 36% from 5.24% ethanol, and 41% from 10.5% ethanol. Ethanol exerted effects on the gastric mucosa only at about twice the hyperosmolality of the other less lipid soluble instillates (NaCl, KCl, $MgCl_2$, or dextrose), presumably due to its relatively unrestricted absorption. Acid secretion was inhibited (at the 10.5% ethanol concentration; the H^+ concentration was 0.0 mEq/l), and the electrical potential difference across the stomach wall was depressed only at the highest concentration of ethanol tested (1,900 mOsmol/kg). Ethanol is reported to produce the same changes in gastric mucosal function as other hyperosmotic agents when instilled into the rat stomach. Due to its lipid solubility, ethanol can rapidly permeate the lipoid matrix of the gastric mucosa and be absorbed, even at low concentrations.

5283 THE TRANSFER OF VOLATILE FATTY ACIDS THROUGH THE WALL OF ISOLATED RAT CECUM. (Fre.) Mottaz, P.; Worbe, J. F. (Laboratoire de Physiologie metabolique, Universite de Lyon I, 43, boulevard du 11 Novembre 1918, 69621 Villeurbanne, France). *C. R. Soc. Biol. (Paris)* 171(2):375-380; 1977.

The transfer of acetic (60 mM), propionic (25 mM), and butyric (15 mM) acids through the cecum was studied *in vitro* in male Wistar rats using an everted sac technique. The quantities of volatile fatty acids (VFA) found in the mucosal and serosal fluids and in the cecal wall were measured chromatographically 1 hr after the acids were introduced to either side of the cecal wall. The results showed that the cecum, unlike the duodenum, was not able to transport VFA from the mucosal to the serosal side against a concentration gradient. It is concluded that the cecal membrane is permeable to VFA and that diffusion solely accounts for the observed transfers.

5284 HUMAN INTESTINAL ION TRANSPORT IN VITRO. (Eng.) Corbett, C. L.; Isaacs, P. E. T.; Riley, A. K.; Turnberg, L. A. (Univ. Manchester Sch. Medicine, Eccles Old Rd., Salford M6 8HD, England). *Gut* 18(2):136-140; 1977.

The transport of sodium and chloride across human jejunal and ileal mucosa was studied *in vitro*. Specimens of mucosa obtained from patients undergoing small bowel resection were stripped of muscle coats, mounted in specially designed Perspex flux chambers, and were bathed in warmed, oxygenated, and stirred buffer solutions. In both jejunum and ileum specimens, there was a significant ($p<0.05$) net absorption of sodium in glucose-free solutions (+1.3 ± 0.4 and +1.2 ± 0.5 µmol/hr/cm^2, resp.). There was a small net secretion of chloride in the jejunum and ileum (-1.8 ± 0.9 and -0.4 ± 0.6 µmol/hr/cm^2, resp.) with neither value being significantly different from zero. Glucose increased net sodium absorption in the jejunum (+5.9 ± 1.2 µmol/hr/cm^2, $p<0.02$) and ileum (+12.1 ± 1.4 µmol/hr/cm^2, $p<0.001$) mainly because of an increase in the mucosa to serosa unidirectional flux. Ileal unidirectional chloride fluxes were not significantly altered by glucose, although net chloride absorption (+1.6 ± 0.7 µmol/hr/cm^2) was significantly greater than zero ($p<0.05$) In the jejunum, the net chloride absorption was unchanged by glucose addition. In the absence of glucose, the potential difference (PD), short circuit current (SCC), and resistance (R) values were 5.6 ± 0.4 mV, 70.6 ± 4.3 µamp/cm^2, and 82.6 ± 5.8 ohms/cm^2, resp., in the jejunum and 3.3 ± 0.3 mV, 89.9 ± 6.1 µamp/cm^2, and 40.3 ± 2.8 ohms/cm^2, resp. in the ileum. After glucose addition, the PD, SCC, and R values were 7.7 ± 0.3 mV, 181.9 ± 12.2 µamp/cm^2, and 52.7 ± 4.3 ohms/cm^2, resp., in the jejunum and 8.4 ± 0.4 mV, 252 ± 15.8 µamp/cm^2, and 36.5 ± 1.6 ohms/cm^2, resp., in the ileum. Thus, in both j junum and ileum, glucose enhanced PD and SCC ($p<0.001$). Ileal resistance was unaffected, but in th jejunum, the resistance was lowered by glucose ($p<0.001$). The results are broadly similar to those reported for *in vitro* animal intestine experiments, but they differ from those obtained *in vivo* in man and animals, suggesting that technical rather than species differences are responsible for many of the discrepancies between *in vivo* human and *in vitro* animal intestinal behavior.

5285 ION TRANSPORT ACROSS ISOLATED ANTRAL MUCOSA OF THE RABBIT. (Eng.) Fromm, D.; Schwartz, J. H.; Roberston, R.; Fuhro, R. (Harvard Medical Sch., Boston, MA 02215). *Am. J. Physiol.* 231(6):1783-1789; 1976.

The transport of sodium, potassium, chloride, and bicarbonate across isolated antral mucosa of New Zealand white rabbits under short-circuit condition was studied. Net fluxes (unidirectional mucosal-to serosal flux minus unidirectional serosal-to-mucosa flux) of sodium, chloride, and potassium ion were -1.3 ± 0.1, -4.0 ± 0.3, and 0.1 ± 0.3 µEq/hr/cm^2, resp., across antral mucosa bathed in bicarbonate-free Ringer solution and -1.5 ± 0.2, -3.0 ± 0.4, an 1.1 ± 0.4 µEq/hr/cm^2, resp., when both sides of antral mucosa were bathed in Ringer solution containing bicarbonate. In contrast to flux measurements made in the absence of bicarbonate, a significant ($p<0.025$) residual flux was observed in the presence of bicarbonate, suggesting the presence o bicarbonate secretion. The addition of bicarbonate to 12 tissues was followed by a significant increas ($p<0.001$) in the unidirectional mucosal-to-serosal chloride flux, with the mean difference between thi flux before and after bicarbonate addition to serosal bathing solution being 1.87 ± 0.27 µEq/hr/cm^2. In contrast, the unidirectional serosal-to-mucosal flux, chloride flux, or either of the unidirectional sodium fluxes was not significantly tered after bicarbonate addition. Measurent of bicarbonate secretion in the absence of bient chloride ion suggests that a major portion the bicarbonate flux is not dependent on chlore. However, the presence of luminal chloride ion rther stimulated bicarbonate secretion, and birbonate secretion increased the unidirectional cosal-to-serosal flux of chloride. Hence, there both a chloride-independent and a chloridependent component of bicarbonate secretion by bbit antrum. In the absence of ambient chloride n, norepinephrine did not significantly alter carbonate secretion, suggesting that an observed repinephrine-induced reduction in bicarbonate cretion in the presence of chloride ion may be e to inhibition of that fraction of bicarbonate cretion dependent on unidirectional chloride ion ansport.

36 EFFECT OF HYPERMAGNESEMIA ON RAT JEJUNAL SODIUM AND WATER TRANSPORT.

(Eng.) Bona, G. F.; Sawin, L. L. (Univ. Iowa Coll. Medine, Iowa City, IA 52242). *Am. J. Physiol.* 231(6): 71-1776; 1976.

e effect of hypermagnesemia on sodium and water ansport in *in vivo* perfused jejunums of female ague-Dawley rats was investigated. The jejunal gments were perfused with a sustaining infusion ntaining 80 mM magnesium chloride. During 14 eximents, when the plasma magnesium concentration s increased threefold from a control value of 78 ± .16 mEq/1 to 5.89 ± .55 mEq/1 ($p<0.01$), the water flux decreased from a control value of .9 ± 6.1 µl/hr/cm to 38.8 ± 4.6 µl/hr/cm ($p<0.01$), l the net sodium flux decreased from a control lue of 7.9 ± 0.9 mEq/hr/cm to 5.6 ± 0.7 mEq/hr/ ($p<0.01$). Measurements of the unidirectional ux of sodium from blood to lumen and from lumen blood indicated that the above decreases were e to a reduction in unidirectional sodium efflux om lumen to blood and not to an increase in uniectional sodium influx from blood to lumen. ing experiments in which the plasma magnesium ncentration was increased threefold from 1.74 ± 3 mEq/1 to 5.66 ± 41 mEq/1, hypermagnesemia did change the jejunal permeability to inulin 0.2). The effect of hypermagnesemia on jejunal lium and water transport is similar to that on nal proximal tubule sodium and water transport, l this similarity suggests that the mechanism of ion of magnesium on these two transporting epielial tissues is similar.

37 CALCIUM TRANSLOCATION BY GOLGI AND LATERAL-BASAL MEMBRANE VESICLES FROM RAT ESTINE: DECREASE IN VITAMIN D-DEFICIENT RATS.

ng.) Freedman, R. A.; Weiser, M. M.; Isselbacher, J. (Massachusetts General Hosp., Boston, MA 114). *Proc. Natl. Acad. Sci. U.S.A.* 74(8):3612-16; 1977.

estinal Ca^{2+} transport was studied in membrane sicles isolated from microvillus, Golgi, and eral-basal membrane preparations of rats. Ca^{2+} take by these vesicles was measured by determination of ^{45}Ca^{2+} associated with these membranes after collection by micropore filtration. Golgi membranes showed the highest initial rate and equilibration level of Ca^{2+} uptake. Approximately 90% of this Ca^{2+} uptake was into an osmotically responsive space, suggesting that what was measured was predominantly Ca^{2+} translocation. Vitamin D-deficient rats (rats fed a 0.02% calcium, 0% vitamin D diet for 2-3 weeks) showed a markedly diminished rate of uptake and level of equilibration. These data indicate that a Ca^{2+}-translocating process was associated with Golgi membranes to a greater extent than with surface membranes and that this process was markedly decreased in vitamin D-deficient rats. The results suggest that the Golgi apparatus participates in intestinal Ca^{2+} absorption.

5288 FAILURE OF LACTOSE AND GLUCOSE TO INFLUENCE IN VIVO INTESTINAL CALCIUM TRANSPORT IN NORMAL RATS.

(Eng.) Urban, E.; Pena, M. (Audie L. Murphy Veterans Admin. Hosp., 7400 Merton Minter Blvd., San Antonio, TX 78284). *Digestion* 15(1): 18-27; 1977.

The influence of luminal lactose and glucose on intestinal calcium transport was examined *in vivo* in normal post-weaned young Sprague-Dawley rats. *In situ* segments of duodenum, midgut, and ileum were perfused through the lumen for 1 hr with an isotonic solution of 3.4 mM calcium containing radioactive ^{45}calcium as tracer plus either 10 mM lactose or 10 mM glucose or, for control rats, no saccharide. Net absorption was measured by the disappearance of luminal calcium, and lumen-to-plasma (LP) flux was determined from the disappearance of calcium tracer. The plasma-to-lumen (PL) flux, which is the most subject to error of any of the transport measurements, was calculated by subtracting calcium absorption/g from LP flux/g. Control rats had PL flux/g values for the duodenum, midgut, and ileum of 22.8 ± 4.7, 9.9 ± 2.8, and 8.4 ± 2.4, resp., compared with corresponding values of 19.3 ± 4.7, 7.8 ± 2.7, and 10.8 ± 4.0, resp., for lactose-perfused rats and values of 23.2 ± 3.7, 6.1 ± 1.2, and 7.3 ± 2.8, resp., for glucose-perfused rats. The data indicate that luminal lactose or glucose had no direct effect on calcium transport under the above steady-state conditions.

5289 LIPID ABSORPTION IN NEWBORN RAT INTESTINE.

(Eng.) Ferlatte, M. I.; Zeman, F. J. (Dept. Nutrition, Univ. California, Davis, CA 95616). *Dev. Biol.* 57(1):1-14; 1977.

Lipid absorption by intestinal cells of the proximal small intestine of newborn Sprague-Dawley rats weighing 6.4 ± 0.3 g was studied to characterize the function and morphology of transition cells. Three groups of rats were used: unsuckled animals, suckled animals, and unsuckled animals infused with 0.1 ml of corn oil. Three distinct regions of cellular maturation within the newborn intestinal epithelium were found. As crypt cells move onto the lower villus surface, they become transition cells, which in turn were reported to differentiate into mature villus-absorptive cells. Crypt cells were capable of mitosis and of some absorption, whereas villus cells were capable only of absorption (after 3 hr of infusion they were filled with lipid droplets). Transition cells were capable of both division and absorption (a large number of lipid droplets were seen). It is suggested that intestinal cells of newborn rats retain their ability to divide while their capacity to absorb and transport nutrients increases. Rough endoplasmic reticulum plays an important role in the transport of lipid through these cells.

5290 TRANSPORT OF PURINE NUCLEOTIDES AND NUCLEOSIDES BY IN VITRO RABBIT ILEUM.

(Eng.) Harms, V.; Stirling, C. E. (Dept. Medicine, Univ. California, San Diego, CA 92093). *Am. J. Physiol.* 233(1):E47-E55; 1977.

To obtain a better understanding of the mechanism of purine absorption and to gain further insight into the effects of exogenous ATP on transport, the kinetics of $[^{14}C]$ATP and $[^{14}C]$adenosine entry into rabbit ileum were measured using 1-min mucosal exposures. ATP influx was the sum of a linear ($p = 1.02 \times 10^{-3}$ cm/min, where P is the permeability coefficient of the pathway) and nonlinear component (J_m=4.07 nmol/min/cm^2, K_m=0.31 mM, where J_m is the maximum influx). Adenosine yielded quantitatively similar results. The kinetics of $[\gamma\text{-}^{32}P]$ATP entry were only linear ($p = 0.55 \times 10^{-3}$ cm/min). These data indicate that at least 85% of the terminal phosphate of ATP is hydrolyzed during transport. Inhibitory measurements indicate that ring-labeled ATP and adenosine compete for a common entry path; however, adenosine does not inhibit the saturable component of $[^{14}C]$ATP to the degree expected of a simple carrier-mediated system. Adenosine (5 mM) produced no inhibition of $[\gamma\text{-}^{32}P]$ATP (0.1-1.0 mM) entry. Measurement of hydrolysis during incubation indicates a negligible fraction of uptake results from labeled adenosine released into the bulk solution. Hydrolysis of ATP followed by a preferred uptake of the adenosine released at the membrane surface probably accounts for most of the observed transport. $[^{14}C]$ATP entry depended neither on $[Na^+]$, $[Mg^{2+}]$, nor $[Ca^{2+}]$ of the bulk solution. Autoradiography of $[^3H]$ATP confirmed that the labeled material entered the epithelial cells and that uptake was nonuniform among cells.

5291 AN ELECTRON MICROSCOPE STUDY OF THE INTESTINAL ABSORPTION OF MEDIUM CHAIN AND LONG CHAIN TRIGLYCERIDES IN THE RAT.

(Eng.) Ohshima, Y. (Kyushu Univ. Faculty Medicine, 3-1-1 Maedashi, Higashi-ku, Fukuoka, 812 Japan). *Arch. Histol. Jpn.* 40(2):153-169; 1977.

Light and electron microscopic studies of ultrastructural changes in the intestinal absorptive cells of Wistar rats fed medium chain (MCT, trioctanoin) or long chain (LCT, soybean oil) triglycerides are reported. In the absorptive cells of rats fed MCT, the agranular endoplasmic reticulum in tubular form was remarkably proliferated throughout the cytoplasm, compared with that of fasting rats. The granular endoplasmic reticulum was mostly transformed into the same tubulo-vesicular form as the agranular endoplasmic reticulum. Chylomicrons, whic were consistently observed in the endoplasmic reticulum of the intestinal absorptive cells of rats fed LCT, did not appear in MCT-fed rats, although small lipid particles were noticed within the endoplasmic reticulum. In rats fed MCT, the Golgi complex was usually located at the supra and lateral nuclear zone of the cytoplasm. The Golgi lamellae were shorter in length and decreased in number. In LCT-fed rats, the Golgi lamellae became reduced in number and length during the early stage of LCT absorption. As absorption progressed, the Golgi lamellae almost completely disappeared, and Golgi vacuoles that were filled with lipid droplets were conspicuous. During the absorption of MCT, the central lacteal contained a few lipid particles, which were smaller in size than the chylomicron observed in the central lacteal during LCT absorption. These observations suggest the possibility that the majority of MCT administered was transported through the absorptive cell into the portal venous system without reesterification in the endoplasmic reticulum and that only a minor part of the MCT administered was transported via the central lacteal after reesterification.

5292 ZINC-BINDING LIGANDS IN MILK AND INTESTIN A ROLE IN NEONATAL NUTRITION?

(Eng.) Hurley, L. S.; Duncan, J. R.; Sloan, M. V.; Eckhert C. D. (Dept. Nutrition, Univ. California, Davis, Davis, CA 95616). *Proc. Natl. Acad. Sci. U.S.A.* 74(8):3547-3549; 1977.

The hypothesis that a zinc-binding ligand (ZBL) recently discovered in human milk but absent from cow's milk might be related to zinc nutrition in the neonate was investigated using the Sprague-Dawley rat as a model. By gel filtration, rat milk was found to contain a ZBL with characteristics similar to those of the ZBL found in human milk. A similar ZBL was identified in the intestinal mucosa of rats 16 days of age and older but was absent in rats from birth to 16 days. These results support the hypothesis that the ZBL of maternal milk may enhance zinc transport in the neonatal period before the development of intestinal mechanisms for zinc absorption.

5293 THE MECHANISM FOR SMALL-BOWEL ADAPTATION IN LACTATING RATS.

(Eng.) Elias, E.; Dowling, R. H. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Clin. Sci. Mol. Med.* 51(5): 427-433; 1976.

To study the relative contributions of luminal nutrition, bile and pancreatic secretions, and hormonal factors in intestinal adaptation, lactation hyperphagia was chosen as a model for increased lum inal nutrition, either alone (intestinal transectio control group) or in combination with (I) exclusion of bile and pancreatic secretions from the jejunum (by transposition of the jejunum above the Ampulla of Vater) or (II) exclusion of bile, pancreatic secretions and exogenous luminal nutrition from the

junum (proximal Thiry-Vella by-pass group). Mu-
sal hyperplasia was reported in lactation. The
an villus height increased from 393 ± 24 μm in
e nonlactating control jejunum to 460-509 μm in
e different groups of lactating rats. Similar
sults were seen in jejunum for crypt depth, which
creased by 50, 56, and 39% in the transected
<0.005), duodenal transposition ($p<0.001$), and by-
ss ($p<0.01$) groups, resp. Comparable increases
re reported in the ileum of various groups of
ts. The mean glucose absorption from nonlactat-
g control jejunum (1.98 ± 0.09 mg/hr/cm) in-
eased by 58% in lactating transected control rats,
44% in the duodenal transposition group, and by
% in the by-pass group ($p<0.001$). These struc-
ral and functional adaptive changes were much
eater in ileum than in jejunum. The magnitude
the increased absorption was similar in all
oups of lactating rats, whether or not pancrea-
co-biliary secretions had been excluded from the
junum or diverted to the ileum. It is suggested
at the changes in small bowel mucosal structure
d function seen in lactation in the rat are due
hormonal factors.

5306 PROLONGED POTENTIALS IN GASTROINTESTINAL MUSCLES INDUCED BY CALCIUM CHELATION.

(Eng.) Prosser, C. L.; Kreulen, D. L.; Weigel, R. J.; Yau, W. (Dept. Physiology and Biophysics, Univ. Illinois, Urbana, IL 61801). *Am. J. Physiol.* 233 (1):C19-C24; 1977.

The effect of removing calcium in the gastrointestinal smooth muscles, using ethylene glycol-bis (β-aminoethyl ether)-N,N^1-tetracetic acid (EGTA) or EDTA was studied in stomach muscles of skate, toad, or frog, or intestinal muscle of the cat. Treatment of these tissues with Ca-free physiological solutions containing 2-5 mM EGTA or EDTA caused a reversible disappearance of spontaneous spikes and slow waves. With continued treatment, depolarization of 25-30 mV from resting potentials of -65 mV occurred, and rhythmic prolonged potentials of several seconds duration appeared. They showed rapid depolarization to near zero and rapid repolarization, and they continued for several hours. The prolonged potentials disappeared when Na was replaced by Li, Tris, or choline. The EGTA-induced waves were abolished by manganese, cobalt, lanthanum, verapamil, and methoxyverapamil. After 10-15 min in 5 mM EGTA, voltage-current curves of circular muscle showed increased leakage current and abolition of anomalous rectification. It is concluded that, when bound Ca is removed by a chelator, nonspecific reduction in resistance occurs, and Na ions may enter rhythmically through channels normally used by Ca.

5307 TOLERANCE TO THE EFFECT OF MORPHINE ON INTESTINAL TRANSIT.

(Eng.) Weisbrodt, N. W.; Badial-Aceves, F.; Dudrick, S. J.; Burks, T. F.; Castro, G. A. (Univ. Texas Medical Sch., P.O. Box 20708, 6400 W. Cullen, Houston, TX 77030). *Proc. Soc. Exp. Biol. Med.* 154(4):587-590; 1977.

Studies were carried out in Sprague-Dawley rats to assess quantitatively whether acute injections of morphine affect intestinal transit, and to determine whether prior chronic morphine treatment produces tolerance to the observed effects. Intestinal transit was determined using ^{51}Cr. At 60 and 120 min, the chromium traversed 50% of the gut length. In comparison with saline-treated controls, the intestinal transit time on the same day of acute administration of morphine sulfate (20 mg/kg, s.c.) was reduced; ^{51}Cr was distributed along the proximal 90% of the gut length after saline administration but only along the proximal 30% after one morphine injection. In rats injected with morphine (20 mg/kg, s.c.) three times daily for 7 days, intestinal transit was decreased to a lesser degree than in the rats that received only one injection; the ^{51}Cr traversed 70%, 70%, and 80% of the gut at 30, 60, and 120 min after the last injection, resp. This study represents an *in vivo* demonstration of morphine tolerance in transit through the small intestine.

5308 IMPROVED INFUSION SYSTEM FOR INTRALUMINAL ESOPHAGEAL MANOMETRY.

(Eng.) Arndorfer, R. C.; Stef, J. J.; Dodds, W. J.; Linehan, J. H.; Hogan, W. J. (Dept. Radiology, Medical Coll. Wisconsin, Milwaukee, WI). *Gastroenterology* 73(1):23-27; 1977.

A low compliance hydraulic-capillary infusion system that yields accurate recordings of esophageal peristaltic pressure at infusion rates of 0.6 ml/min or less is described. The hydraulic-capillary infusion system is based on an entirely different principle than syringe-pump systems. Reservoir water maintained at a high constant pressure is reduced to atmospheric pressure by capillary tubing with a high resistance to flow. Capillary flow rate is proportional to the pressure gradient across the capillary. Consequently, pressure events in the esophagus have relatively little effect on flow rate, because catheter pressure during peristalsis (about 50-200 mm Hg) remains low in comparison with the pressure head of the reservoir (1,000 mm Hg). Esophageal manometric studies were performed with the infusion system on five normal volunteers using three polyvinyl catheters with internal diameters of 0.6, 1.1, and 1.6 mm. Peristaltic pressures were recorded accurately with both the 0.8- and 1.1-mm catheters infused at 0.6 ml/min with the hydraulic-capillary infusion system. In contrast, an infusion rate of 3.2 ml/min was necessary to achieve recording fidelity using a syringe-pump system. Distal occlusion of the respective manometric catheters revealed that the pressure rise rate was inversely related to catheter internal diameter. Catheter compliance, in addition to being directly related to luminal internal diameter, was inversely related to catheter wall thickness and directly related to catheter elasticity and length. The 0.6-ml/min infusion rate used in the above study applies to polyvinyl catheters, and it is estimated that flow rates as low as 0.2 ml/min might be adequate if the manometric recording assembly were made of stiffer materials such as polyethylene. The hydraulic-capillary infusion system appears to be a useful tool for performing both clinical and investigative studies of esophageal motor function.

5309 EFFECT OF METOCLOPRAMIDE ON THE LOWER OESOPHAGEAL SPHINCTER: AN EXPERIMENTAL STUDY IN DOGS.

(Eng.) Punto, L.; Mokka, R. E. M.; Kairaluoma, M. I.; Larmi, T. K. I. (Dept. Surgery, Univ. Oulu, SF-90220 Oulu 22, Finland). *Med. Biol.* 55(1):66-68; 1977.

Because metoclopramide seems to be a promising supplement to the conservative treatment of reflux esophagitis, the esophageal, lower esophageal sphincter (LES), and gastric fundal pressures were measured in dogs before and after the i.v. injectio of metoclopramide (1 mg/kg). Pressures were measured with a triple lumen, open tip-infused catheter. The mean basal pressures of the fundus, the LES, and the lower esophagus were 2.4 ± 1.5, 7.7 ± 3.8, and -2 ± 1.3 mm Hg, resp. The mean pressure difference between the LES and the fundus was 5.3 ± 2.7 mm Hg, which constituted the LES pressure. Increased LES pressure was noted at 1 min after the injection (11.8 ± 5.2 mm Hg, $p<0.01$). The highest pressure occurred at 10 min after injection (13.7 ± 5.1 mm Hg, $p<0.01$), and the LES essure was still elevated 30 min after the jection (8.6 ± 3.9 mm Hg, $p>0.05$). Metoclopramide d no effect on the pressure of the canine fundus on the lower esophagus.

10 THE INFLUENCE OF OXYGEN SUPPLY TO THE SMALL INTESTINE IN THE ILEUS MODEL.

er.) Richter, H.; Jostarndt, L.; Tichai, I.; ermann, M. (Chirurgische Universitatsklinik, bert-Koch-Strasse 8, D-3550 Marburg/Lahn, W. rmany). *Chirurg* 47(6):328-330; 1977.

e effect of a mixture of Dextran 40 and 20% rbit on the local oxygen supply (PO_2) of the testinal wall was studied in the ileus model the rabbit. Experimental distention of the eum was performed in pentobarbital anesthetized bbits. An intraluminal pressure of 10, 20, or cm H_2O was applied via a polyvinylchloride se into the terminal ileum, and local PO_2 was asured with a superficial electrode on the rosa in nondistended intestinal wall before and ter administration of Sorbit (7.5 ml/kg i.v.) d glucagon (25 μg/kg). In the nondistended ileum, e local PO_2 was 42.2 ± 6.6 torr; at intralumal pressures of 10 cm, 20 cm, and 30 cm, it ll to 24.6 ± 5.9 torr, 16.5 ± 6.7 torr, and to .1 ± 8.6 torr, resp. After decompression, the $_2$ increased to 49.5 ± 9.1 torr, significantly gher than the initial value ($p< 0.025$). A significant increase of local tissue and arterial PO_2 s noted in the nondistended ileum following inction of Sorbit; glucagon caused no significant ange in local PO_2 in the distended or nondistended eum. The administration of Sorbit and decompreson of the distended intestine are recommended to prove the oxygen supply of the intestinal wall patients with ileus.

11 THE EFFECTS OF INDOMETHACIN ON THE TONE AND SPONTANEOUS ACTIVITY OF THE HUMAN ALL INTESTINE IN VITRO.

(Eng.) Burleigh, D. E. ondon Hosp. Medical Coll., Turner St., London, 2AD, England). *Arch. Int. Pharmacodyn. Ther.* 5(2):240-245; 1977.

e effects of indomethacin on the tone and sponneous activity of muscle strips from normal human rminal ileum were investigated. After nearly all rcular muscle spontaneous activity had disappeared after the muscle tone of the longitudinal strips d reached a stable level, indomethacin produced large and sustained increase in spontaneous tivity and, occasionally, a slight rise in tone circular muscle exposed to 0.05 and 0.55 μg/ml domethacin; in longitudinal muscle, tone was pidly lost and spontaneous activity was often duced after exposure to indomethacin concentrations 0.04 and 0.2 μg/ml. When indomethacin was added the beginning of the experiment, longitudinal scle strips failed to develop tone, and their ontaneous activity was reduced. Under the same nditions, spontaneous activity of the circular eum was increased and well maintained throughout e experiment. Indomethacin (5-10 μg/ml) did not duce contractions to acetylcholine (0.1-0.8 μg/ml) or prostaglandin $F_{2\alpha}$ (PG, 0.08-1 μg/ml) when tested on circular muscle strips from the ileum. The effects of PGE_2 differed from those of $PGF_{2\alpha}$ on circular muscle strips of the ileum. PGE_2 (0.04-1.0 μg) caused a small relaxation, together with a dose-related inhibition of spontaneous activity, while $PGF_{2\alpha}$ (0.08-1.0 μg/ml) caused a dose-related contraction, followed by a slight relaxation, with the latter being more apparent at lower doses. Unlike circular muscle, longitudinal strips gave contractions to both PGE_2 (0.02 μg/ml) and $PGF_{2\alpha}$ (0.02 μg/ml). The results suggest that prostaglandins may be involved in the maintenance of tone of longitudinal muscle and the suppression of spontaneous activity in circular muscle from the human terminal ileum.

5312 ACTIONS OF CHOLECYSTOKININ OCTAPEPTIDE ON SMOOTH MUSCLE OF ISOLATED DOG INTESTINE.

(Eng.) Stewart, J. J.; Burks, T. F. (Univ. Texas Medical Sch., Texas Medical Center, Houston, TX 77025). *Am. J. Physiol.* 232(3):E306-E310; 1977.

The action of cholecystokinin octapeptide on the smooth muscle of isolated dog intestine was investigated. Adult dogs were anesthetized, and segments of small intestine were isolated and perfused via a mesenteric artery with Krebs-bicarbonate solution. Agonists were administered as intra-arterial bolus injections, and antagonists were dissolved in the Krebs perfusion solution. The C-terminal octapeptide of cholecystokinin (CCK-OP) produced dose-related tonic and phasic contractions of smooth muscle along the transverse axis, and tonic and phasic relaxations along the longitudinal axis, of the muscle segments. The durations of response varied from about 1 min at a CCK-OP dose of 0.04 μg to more than 6 min at a dose of 5.0 μg. Smooth muscle responses to CCK-OP were reduced by atropine sulfate (0.1 μg/ml) and minimally affected by hexamethonium (10 μg/ml) perfusion. Tetrodotoxin (5 ng/ml) selectively reduced muscle responses to dimethylphenylpiperazinium (0.5 μg) and CCK-OP (0.2 μg), but failed to alter responses to bethanechol (5 μg). Higher concentrations of tetrodotoxin (10 ng/ml) abolished responses to CCK-OP. Depolarizing doses of nicotine (500 μg) selectively antagonized responses to 5-hydroxytryptamine (5HT, 5 μg) and CCK-OP (0.2 μg), but did not alter responses to bethanechol (5 μg). Perfusion with tetraethylammonium (1 mg/ml) reduced muscle responses to depolarizing doses of nicotine and abolished the nicotine-induced antagonism of 5HT and CCK-OP. It is concluded that the intestinal smooth muscle response to CCK-OP in the dog is mediated through a neurogenic mechanism and that CCK-OP interacts with a non-nicotinic receptor on postganglionic cholinergic neural elements in this preparation.

5313 A COMPARISON OF INTRINSIC NERVE SUPPLIES OF TWO MUSCULAR LAYERS OF DUODENUM.

(Eng.) Anuras, S.; Christensen, J.; Cooke, A. R. (Veterans Admin. Hosp., Univ. Iowa, Iowa City, IA 52242). *Am. J. Physiol.* 233(1):E28-E31; 1977.

The responses of feline and opossum duodenal longitudinal muscles to electrical field stimulation of the intrinsic nerves were compared to those of the circular muscles. The duodenums were cut into strips 2 mm wide and 2-2.5 cm long. Strips cut in the direction of the oral-caudal axis were called longitudinal strips, and those cut at 90 degrees to that axis were called circular strips. Each muscle strip was stimulated with trains of electrical rectangular pulses (10 Hz, 50-70 V, 0.5 msec). In the longitudinal strips, electrical field stimulation caused contraction, and this contraction was abolished by 10^{-7} M atropine. In the circular strips, electrical field stimulation caused relaxation. This relaxation was abolished by 10^{-7} M tetrodotoxin, but it was not affected by antagonists to adrenergic and cholinergic transmission or by pentagastrin, cholecystokinin, secretin, or cerulein (10^{-5}, 10^{-7}, 4×10^{-7}, and 1.5×10^{-8} M, resp.). Reserpinization of the opossums or alteration of the frequencies of electrical field stimulation from 0.1 to 50 Hz did not affect or alter the relaxation of the circular strips or the contraction of the longitudinal strips. These findings suggest that the longitudinal muscle is dominated by an excitatory cholinergic innervation and that the circular muscle is dominated by a nonadrenergic, noncholinergic inhibitory innervation.

5314 EFFECTS OF CHOLECYSTOKININ ON THE MOTILITY OF THE DISTAL DUODENUM AND PROXIMAL JEJUNUM IN MAN.

(Eng.) Fleckenstein, P.; Oigaard, A. (Rigshospitalet, Blegdamsvej, DK 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(3):375-378; 1977.

Since motility markedly increases in response to cholecystokinin (CCK) in the distal but not the proximal small intestine, experiments were carried out to determine more precisely at which point in the gastrointestinal tract the change in reaction to CCK occurs. Electrical spike potentials and intraluminal pressure variations were recorded in the distal duodenum and the proximal jejunum in five healthy subjects before and after an injection of CCK-pancreozymin (1 Ivy dog U/kg). CCK administration caused no change in duodenal motility but markedly increased activity in the proximal jejunum within 1-2 min. There were no changes in the amplitude of spike potentials either in the distal duodenum or in the proximal jejunum ($p>0.05$). It is concluded that the human duodenum differs from the rest of the small intestine in its reaction to cholecystokinin. The change in reaction appears to occur on a level with the ligament of Treitz.

5315 INHIBITORY EFFECT OF THE CALCIUM ANTAGONIST FENDILINE ON DIGITALIS GLYCOSIDE-INDUCED CONTRACTIONS IN THE GUINEA PIG TERMINAL ILEUM.

(Ger.) Sprugel, W.; Mitznegg, P.; Heim, F. (Pharmakologisches Institut, Universitat Erlangen-Nurnberg, 8520 Erlangen, W. Germany). *Arzneim. Forsch.* 27(7): 1405-1407; 1977.

Fendiline (0.01-1 μg/ml) caused a significant dose-dependent inhibition of contractions of isolated 10-mm segments of guinea pig terminal ileum that had been induced by the digitalis glycosides beta-acetyl-digoxin (0.4 μg/ml) or k-strophanthin (0.5 μg/ml). The effects of fendiline were reversible after three washings and reintroduction of beta-acetyl-digoxin (0.4 μg/ml). However, the contractions induced by the latter agent were markedly smaller as compared to the level of initial induction. Fendiline caused an almost 100% inhibition at a concentration of 1 μg/ml and a 30% inhibition at 0.01 μg/ml ($p<0.05$). Fendiline (1 μg/ml) totally suppressed the effects of k-strophanthin (0.5 μg/ml). The results suggest that the inhibitory effects of fendiline are probably due to its specific calcium antagonistic properties and that it may be useful clinically for manifest symptoms of digitalis intoxication caused by an increase of intracellular calcium ions.

5316 EFFECTS OF PROSTAGLANDINS ON THE PERISTALTIC REFLEX OF THE GUINEA-PIG ILEUM.

(Eng.) Fontaine, J.; Van Nueten, J. M.; Reuse, J. J. (Institut de Pharmacie, ULB, Brussels, Belgium). *Arch. Int. Pharmacodyn.* 226(2):341-343; 1977.

The effects of prostaglandin (PG) and some nonsteroidal anti-inflammatory prostaglandin synthesis inhibitors on the peristaltic reflex were studied in the isolated guinea pig ileum. Peristaltic reflex activity was induced by a sustained intraluminal pressure (2 cm H_2O). The addition of PGE_1 and PGE_2 (0.63-2.5 μg/l) facilitated the induction of peristaltic reflex activity and longitudinal muscle response, slightly decreased the circular muscle activity, and lowered the threshold for the expulsion of intraluminal fluid. After the additio of PGE_1 and PGE_2, more regular peristaltic reflex waves occurred in preparations in which peristalsis was spontaneously irregular. Indomethacin (0.63 and 2.5 mg/l) inhibited the rapid, noncholinergic part of the longitudinal muscle activity during the peristaltic reflex. A similar effect was observed with other nonsteroidal anti-inflammatory drugs, including suprofen, phenylbutazone, acetylsalicylic acid, and flufenamic acid. Higher concentrations of indomethacin (10 mg/l) and of the other drugs delayed the triggering of the reflex, inhibited the response of both the longitudinal and circular muscle layers, and caused incomplete expulsion of fluid during each wave. PGE_1 and PGE_2 reversed the inhibition caused by the anti-inflammatory drugs, suggesting that the activity of these drugs is related to the inhibition of PG synthetase. The results indicate that PG may play a modulating and normalizing role in the development of peristaltic reflex activity in isolated guinea pig ileum.

5317 THE EFFECTS OF PROSTAGLANDINS E_1, E_2, $F_{1\alpha}$ AND $F_{2\alpha}$ ON GUINEA-PIG ILEAL AND COLONIC PERISTALSIS.

(Eng.) Eley, K. G.; Bennett, A.; Stockley, H. L. (King's Coll. Hosp. Medical Sch., London SE5 8RX, England). *J. Pharm. Pharmacol.* 29(5):276-280; 1977.

The effects of prostaglandins (PG) E_1, E_2, $F_{1\alpha}$, and $F_{2\alpha}$ on the peristaltic reflex in isolated segments

guinea pig ileum and colon were studied using
multaneous recordings of fluid propulsion and
ngitudinal and circular muscle activity. In the
eum, $PGF_{1\alpha}$ and $PGF_{2\alpha}$ (0.33 µg/ml) when applied
rosally resulted in median propulsion increases
3% ($p<0.05$) and 12% ($p<0.01$), resp., and median
creases in circular muscle peristaltic activity
13% ($p<0.05$) and 11% ($p<0.01$), resp., after an
itial contraction of longitudinal muscle. Longi-
dinal muscle peristalsis in the ileum was not
gnificantly affected by the serosal application
either PGF compound, and the mucosal application
either compound (5 µg/0.5 ml) did not signifi-
ntly affect either propulsion or circular or
ngitudinal muscle peristaltic activity in the
eum. In the colon, the serosal application of
$F_{1\alpha}$ and $PGF_{2\alpha}$ (0.33 µg/ml) resulted in median
opulsion increases of 31% and 32% ($p<0.05$), resp.,
d median increases in circular muscle peristaltic
tivity of 53% ($p<0.05$) and 91% ($p<0.01$), resp.;
ngitudinal muscle peristaltic activity was not
gnificantly changed. Mucosal application of the
F compounds (5 µg/0.5 ml) did not result in
gnificant propulsive or peristaltic changes.
ither the serosal application (0.33 µg/ml) nor
e mucosal application (5 µg/0.5 ml) of PGE_1 or
E_2 resulted in significant changes in propulsion
the colon. However, the serosal application
PGE_1 and PGE_2 resulted in median increases in
rcular muscle peristaltic activity of 58% ($p<0.05$)
d 29% ($p<0.01$), resp., and in longitudinal muscle
ristaltic activity of 0% ($p<0.05$) and 12% ($p<0.01$),
sp., in the colon. The mucosal application of
E_1 and PGE_2 resulted in median increases in
ngitudinal muscle peristaltic activity of 10%
<0.05) and 0% ($p<0.05$), resp., in the colon. The
ove findings are consistent with a role for
ostaglandins in peristalsis.

318 MODULATION OF COLONIC MOTILITY BY PERIPHERAL NEURAL INPUTS TO NEURONS OF THE INFERIOR ESENTERIC GANGLION.

(Eng.) Weems, W. A.; Szurs-
ewski, J. H. (Univ. Texas Medical Sch., Houston,
77025). *Gastroenterology* 73(2):273-278; 1977.

tracellular recordings from single neurons in the
ferior mesenteric ganglion (IMG) of *in vitro* IMG-
olon preparations from guinea pigs were made simul-
aneously with measurements of intraluminal pressure
investigate interactions between colonic motility,
eripheral input to the IMG, and postganglionic
eural activity. Gross afferent input to the IMG
rom colonic mechanoreceptors was nonadapting and
orrelated with intraluminal pressure and propulsive
otor activity. At basal intraluminal pressures of
igher than approximately 5 cm of water, afferent
nput to neurons in the IMG increased with basal
ressure increases, until a maximum basal pressure
as reached, which ranged from 8 to 20 cm of water,
epending on each neuron tested. Preganglionic
nput from each nerve trunk attached to the IMG
ndependently altered colonic motility with varying
egrees of effectiveness. Fox example, stimulation
f the intermesenteric nerve in six IMG colon
reparations at frequencies of 1-3 Hz reduced or
bolished the nonpropulsive motor activity and
educed both orad and, to a much lesser extent,
cauded mean pressure. Similar inhibitory responses occurred at frequencies of 5 and 7 Hz in two other preparations tested. When a single inferior splanchnic nerve was tested, minimum frequencies ranging from 8 to 15 Hz were required to produce a detectable reduction in the nonpropulsive pressure wave amplitude and, usually, an accompanying decrease in mean intraluminal pressure at the orad end of the colonic segment. In six of eight IMG-colon preparations, stimulation of a single hypogastric nerve at 5-20 Hz reduced the amplitude of the nonpropulsive pressure waves in the orad end of the colonic segment. To determine whether colonic inhibition results from activation of "straight-through" pathways, as opposed to synaptic junction, in the IMG, four IMG colon preparations were superfused on the IMG side of a two-compartment bath with Krebs solution that either contained 1.44×10^{-4} M tubocurarine chloride or was calcium-free and contained 6 mM of magnesium ion. Within 15 min after the start of superfusion with the tubocurarine chloride-containing solution, both fast synaptic depolarizations and inhibition of colonic motility during stimulation of the intermesenteric, hypogastric, and inferior splanchnic nerves were abolished. Similar results were obtained when the calcium-free, high-magnesium solution was used. It is concluded that the firing patterns of sympathetic postganglionic neurons affecting motility of the terminal colon result primarily from the synaptic integration of inputs from preganglionic fibers of both central and peripheral origin.

5319 QUANTITATIVE STUDY OF GASTRIC EMPTYING BY MEANS OF ULTRASONICS: PRELIMINARY REPORT.

(Eng.) Okukubo, F.; Bruckner, W.; Busse, M.; Bundschuh, V. (Surgical Polyclinic, Munich Univ., W. Germany). *Chir. Gastroenterol.* 11(1): 37-39; 1977.

A quantitative method of studying gastric emptying, using ultrasonography, was developed and tested in 5 normal subjects and 20 duodenal ulcer patients without stenosis. The subjects swallowed an 800-ml test meal (soup) during 5 min. The abdomen was divided into 1-cm slices by making horizontal marks from the xyphoid process downward. The volume of the gastric contents was measured by ultrasonic scanning, which visualizes the horizontal slices of the stomach with 1-cm intervals from the fundus downward. The total volume of the stomach is calculated from the sum of all slices. Scanning was repeated every 10 min up to 80 min after meal ingestion. About 23% of the initial volume was emptied during the first 10 min in the normal subjects, and this emptying rate gradually decreased over the 80 min. This pattern was reproducible and was demonstrated in all five normal subjects at four different times on different days. The emptying rate in the duodenal ulcer patients was significantly lower than in controls. After 80 min, 40% of the test meal remained in the stomach, whereas only 15% remained in the stomachs of the controls. Only 11% of the initial volume was emptied during the first 10 min. There was no correlation between gastric emptying rate and basal or stimulated gastric acid secretion.

5320 CHARACTERIZATION OF GASTRIC EMPTYING BY DETERMINATION OF THE TRANSIT TIME. (Ger.)

Aeberhard, P.; Steudler, G.; Rosler, H.; Noelpp, U. (Klinik fur viszerale Chirurgie, Inselspital CH-3010, Bern, Switzerland). *Schweiz. Med. Wochenschr.* 107(15):539-540; 1977.

The mean transit time (MTT) and half-time (T½) of gastric emptying were determined in 18 healthy men, aged 23-41 yr, given a solid test meal labeled with 500 μCi ^{99m}Tc-sulfur colloid by means of a gamma camera and on-line computer. MTT was calculated by fitting the time-activity histogram to a gamma variable, whereas T½ was obtained from the exponential curves. The MTT was 111.8 ± 18.55 min with a coefficient of variance of 0.17. On the other hand, the T½ was 78.1 ± 17.73 min with a coefficient of variance of 0.23. Thus, MTT showed a smaller coefficient of variance than T½ and this was statistically significant ($p<0.005$). The results suggest that MTT may be a more accurate measure of gastric emptying time and a more accurate method for distinguishing normal from pathological patterns of emptying.

5321 MEASUREMENT OF GASTRIC EMPTYING IN SMALL PRIMATES. (Eng.)

Hall, A. W.; Moossa, A. R.; Skinner, D. B. (Pritzker Sch. Medicine, Univ. Chicago, 950 East 59th St., Chicago, IL 60637). *J. Surg. Res.* 22(2):118-123; 1977.

Gastric emptying in eight rhesus monkeys given a test meal (via nasogastric intubation), consisting of 100 ml of 10% dextrose in water with 15 ppm of phenol red, was investigated. Calculated volumes of fluid in the stomach and the logarithms of the volumes were plotted against time. Assuming an exponential mode of disappearance from the stomach, the best line for the plotted points was fitted by the method of least squares. Gastric emptying was described mathematically by the constants of this line, the half-life of the meal in the stomach ($T½=0.301/b$, where b is the rate constant for the line), and by the time (T) taken for the intragastric contents to fall to 10 ml. Each monkey was studied twice at intervals of 2-6 weeks. There was no significant difference between the two experimental sets of values obtained for the rate constant, T½, or T, as compared by t tests ($p>0.5$). Analysis of variance confirmed that the variation between occasions tested was insignificant. A marked difference between animals ($p<0.001$) was demonstrated. From the residual variation, the standard deviation of the experimental error was estimated. This was ± 0.000476 for the rate constant, ± 15.4 min for T½, and ± 54.6 min for T. The mean T½ values for both sets of studies were 119.4 ± 51.1 min and 123.6 ± 60.6 min, resp. It is suggested that the above method is useful for investigating the impact of operative procedures on gastric emptying in higher animals.

5322 GASTRIC EVACUATION AND PROPULSIVE INTESTINAL MOTILITY IN ACUTE AFFERENT LOOP SYNDROME IN THE RAT. (Eng.)

Dahlgren, S. (Karnsjukhuset Skovde, Fack, S-54101 Skovde, Sweden). *Ups. J. Med. Sci.* 81(2):97-102; 1976.

Gastric evacuation and propulsive intestinal motilit in Sprague-Dawley rats with acute afferent loop syndrome (ALS), i.e., occlusion of the afferent loop after partial gastrectomy by the Billroth II method, were investigated. A standardized radioactive test meal was deposited in the stomach of test rats immediately after the afferent loop had been ligated or, in control rats, after the dissection of the afferent loop. Gastric evacuation was exponential and was markedly delayed in rats with ALS compared with laparotomized controls. The percentages of radioactive dose in the stomach of ALS rats at 0.5 and 4 hr after test meal deposition were 89.9 ± 2.36 and 65.5 ± 6.05, resp., compared with control values of 67.8 ± 4.20 and 30.8 ± 7.75, resp. The differences between test rats and contro rats were significant ($p<0.0005$) at both times after meal deposition. An examination of the percentage distribution of the test meal dose in 10 equal consecutive fractions of the small intestine and in the colonic fraction revealed that propulsio was considerably delayed in rats with ALS as compared with controls. The propulsion in the distal direction 0.5 hr after test meal deposition reached the second fraction of the small intestine in contr rats and the first fraction in ALS rats. After 4 hr, the colonic fraction was reached in controls an in the second small intestinal fraction in ALS rats After 8 and 12 hr, the second and fifth fractions, resp., were reached in the ALS rats. Gastric evacuation and propulsive intestinal motility in ALS rats were also delayed in relation to previous findings involving mechanical intestinal obstruction and paralytic ileus due to retroperitoneal irritation or bacterial peritonitis.

5323 INHIBITION OF GASTRIC AND INTESTINAL MOTO ACTIVITY IN DOGS BY (Gln^{4}) NEUROTENSIN.

(Eng.) Andersson, S.; Rosell, S.; Hjelmquist, U.; Chang, D.; Folkers, K. (Dept. Pharmacology, Karolinska Institutet, Stockholm, Sweden). *Acta Physiol Scand.* 100(2):231-235; 1977.

The action of (Gln^{4})-neurotensin on the spontaneous motor activity in isolated canine fundic, antral, and intestinal pouches was studied. All pouches had been prepared more than 6 months prior to the experiments. Spontaneous motor activity was record for at least 1 hr before the (Gln^{4})-neurotensin was infused i.v. for 30 min in doses ranging between 6.3 and 100 ng/kg/min. In the vagally denervated fundic pouches, (Gln^{4})-neurotensin inhibited motor activity in doses above 25 ng/kg/min. The vagally innervated antral pouches were more sensitive than the vagally denervated fundic pouches to the actio of (Gln^{4})-neurotensin. Thus, motor inhibition was induced by doses as low as 6.3 ng/kg/min. The effect of (Gln^{4})-neurotensin on motor activity in intestinal pouches was inconsistent. Inhibition was seen in one of seven experiments. The results show that the gastric motor activity is the most sensitive function to (Gln^{4})-neurotensin so far studied.

324 EFFECTS OF PROXIMAL GASTRIC VAGOTOMY (PGV)
FOLLOWED BY TOTAL VAGOTOMY (TV) ON POST-
RANDIAL AND FASTING MYOELECTRICAL ACTIVITY OF THE
ANINE STOMACH AND DUODENUM. (Eng.) Aeberhard, P.;
edi, B. S. (Inselspital, CH-3010 Berne, Switzer-
and). *Gut* 18(7):515-523; 1977.

he effect of proximal gastric vagotomy (PGV) fol-
owed by total vagotomy (TV) on the myoelectrical
ctivity of the canine stomach and duodenum was
tudied after a meat meal and during fasting. Dogs
ere prepared with chronically implanted Ag-AgCl-
lectrodes on the stomach and duodenum. Recordings
f electrical activity were made for 1 hr after the
ngestion of a meat meal, and records of 4-6 hr were
aken on the fasting animals. In the postprandial
ecords, no effect on coordination of antral and
uodenal myoelectrical activity was found after
ither PGV or TV. These results suggest that the
oordinating mechanism is not dependent on vagal
nnervation. Impairment of gastric emptying after
V does not appear to be due to disturbance of
ntral-duodenal conduction. Normal patterns of
asting activity were found in control and after PGV.
hey were grossly disturbed after TV, probably be-
ause of delayed gastric emptying. These findings
uggest that PGV does not delay gastric emptying
s does TV, and that the proximal vagal supply to
he stomach is unimportant in the control of fasting
ctivity.

325 EFFECT OF SECRETIN ON MYOELECTRICAL AND
MECHANICAL ACTIVITY OF THE ISOLATED CANINE
TOMACH PERFUSED EX VIVO. (Eng.) Kowalewski, K.;
olodej, A. (Surgical-Medical Res. Inst., Univ.
lberta, Edmonton, Alberta T6G 2N8, Canada). *Phar-
acology* 15(1):73-83; 1977.

otally isolated whole canine stomachs perfused
x vivo with homologous blood were used for recording
yoelectrical and mechanical activity prior to and
ollowing secretin injection into the gastric
rterial circulation. Flash injections of secretin
n doses up to 32 U had no significant effect on
lectrical control activity (ECA) frequency or
hase lag; a similar result was obtained when secre-
in was given as a 60 U/hr constant infusion. This
bsence of a secretin action on ECA was found under
arious conditions of background gastric stimulation
intragastric instillation of fluid, infusion of
entagastrin or bethanechol chloride, and electrical
timulation of the Latarjet branch of the vagus
erve). Flash injections of secretin (16 or 32 U)
gainst a background vagal stimulation of Latarjet
erve (steady stimulation with 10 V, 6 Hz, and 5
sec pulses) resulted in a temporary inhibition of
esponse activity. After 16 U of secretin, the
ntral ECA cycles with electrical response ac-
ivity (ERA) was 72.40 ± 9.5% as compared with
00% prior to secretin treatment ($p<0.001$); after
2 U secretin, the percentage of antral ECA cycles
ith ERA was 34.60 ± 3.2 ($p<0.001$). Secretin
iven as flash injections (16 or 32 U) or as a
onstant infusion (60 U/hr) produced significant
ecreases ($p<0.001$) of contraction amplitudes or
echanical activity recorded at the site of an
ntral strain gauge. For example, a flash injection
of 32 U of secretin reduced the contraction amplitude from 7.00 ± 2.0 to 0.89 ± 1.3 mm. Flash injections of either pentagastrin or methacholine produced premature control potentials, uncoupling of ECA, marked response activity, and antral contractions. When applied against a constant infusion of secretin, these stimulants induced a decreased response that was particularly apparent regarding the timing and amplitude of antral contractions.

5326 A NON-ADRENERGIC INHIBITORY INNERVATION IN THE RAT STOMACH. (Eng.) Heazell, M. A. (Res. Inst., May & Baker Ltd., Dagenham, Essex, RM10 7XS, England). *Arch. Int. Pharmacodyn.* 226(1): 109-117; 1977.

5327 THE EFFECT OF CYCLIZINE HYDROCHLORIDE ON LOWER OESOPHAGEAL SPHINCTER PRESSURE IN MAN. (Eng.) Brock-Utne, J. G.; Downing, J. W.; Dimopoulos, G. E.; Moshal, M. G. (King Edward VIII Hosp., Durban, South Africa). *South Afr. Med. J.* 51(26):977-978; 1977.

SECRETION AND METABOLISM

Stomach

5356 BIOCHEMICAL GRADIENTS IN THE HUMAN GASTRIC AND DUODENAL MUCOSA IN RELATION TO BASAL ACID OUTPUTS. (Eng.) Mozsik, G.; Vizi, F.; Kutas, J. (Univ. Medical Sch., H-7643 Pecs, Hungary). *Scand. J. Gastroenterol.* 12(4):461-464; 1977.

Separations and measurements of adenine-adenosine, AMP, ADP, ATP, lipid phosphates (lipid-P), RNA, and DNA were carried out in the mucosa of the corpus, antrum, and duodenum of 32 peptic ulcer patients. The patients were divided into three groups based on their basal acid output (BAO): BAO< 2,0 mEq/hr, BAO=2.0-4.0 mEq/hr, and BAO >4.0 mEq/hr. The results were calculated in correspondence to 1.0 mg DNA value. The biochemical composition of the corpus and antral mucosa was altered with increased BAO. In patients with normal and increased BAO, a significant difference in the biochemical compositions of the mucosa of the corpus and antrum was observed. No significant difference was found in the duodenal mucosa with decreased BAO. These results indicate the presence of an energetical and biochemical gradient in the human gastric corpus, antral, and duodenal mucosa in relation to BAO.

5357 CALCIUM STIMULATION OF GASTRIN AND GASTRIC ACID SECRETION: EFFECT OF SMALL DOSES OF CALCIUM CARBONATE. (Eng.) Behar, J.; Hitchings, M.; Smyth, R. D. (Rhode Island Hosp., 593 Eddy St., Providence, RI 02902). *Gut* 18(6):442-448; 1977.

The interaction of calcium, serum levels of immunoreactive gastrin, and gastric acid secretion was investigated in 25 duodenal ulcer patients with respect to (a) the site of calcium stimulation and (b) whether the calcium effect on gastric acid secretion is mediated by gastrin. Calcium carbonate (0.5 g, p.o., pH 9.4) increased serum gastrin ($p<0.05$) and gastric acid output ($p<0.001$), with slight but insignificant change in serum calcium. A similar rise in serum calcium during an i.v. infusion of calcium gluconate failed to increase serum gastrin and gastric acid output. Both intragastric calcium actions were abolished by acidification of the calcium carbonate solution (pH 1.0). The increase in serum gastrin and gastric acid output after intragastric calcium carbonate was not affected, however, by a simultaneous intraduodenal acid load. Equivalent neutralizing doses of magnesium hydroxide (pH 9.4) did not increase serum gastrin and gastric acid output above basal levels, whereas antral acidification with 20 ml 0.1 N HCl resulted in a slight decrease in serum gastrin. Intraduodenal calcium carbonate (pH 3.0) also increased serum gastrin and gastric acid output, whereas an equivalent volume of intraduodenal saline (pH 3.0) had no effect. These findings indicate that calcium increases serum gastrin by local stimulation of antral and duodenal mucosa and suggest that the action of calcium on gastric secretion is partly mediated by gastrin.

5358 EFFECT OF FAT ON MEAL-STIMULATED GASTRIC AND PANCREATIC SECRETION. (Eng.) Llanos, O. L.; Swierczek, J. S.; Miller, T. A.; Said, S. I.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *World J. Surg.* 1(4): 507-513; 1977.

The effects of fat on meal-stimulated gastric and pancreatic secretion, and on gastrin, secretin, gastric inhibitory peptide (GIP), and vasoactive intestinal polypeptide (VIP), were investigated in five dogs with chronic gastric and pancreatic fistulas. Gastric secretion was continuously stimulated with a 10% liver extract meal and kept at a constant pH 7 by intragastric titration. After the 1st hr of stimulation, intraduodenal sodium oleate was infused in graded doses (2-16 mmol/hr). Plasma gastrointestinal hormones were determined by radioimmunoassay. The liver extract meal evoked a gastric acid output of 12 ± 1.4 mEq/30 min and a rise in plasma gastrin from 90 ± 20 to 250 ± 50 pg/ml. Sodium oleate produced inhibition of acid secretion by 40% and 70% at doses of 8 and 16 mmol/hr, resp. Sodium oleate produced a dose-dependent increase in the volume of pancreatic juice and bicarbonate and protein output. Meal-stimulated plasma gastrin levels were not affected by sodium oleate. Plasma secretin and VIP levels remained unchanged during the infusion of sodium oleate. GIP was released by liver extract meal and, in addition, in a dose-related fashion by graded doses of sodium oleate. It is concluded that VIP and secretin are not released by fat and that they are not involved in the inhibition of gastric secretion. GIP may be one of the mediators in the inhibition of gastric acid secretion by fat. The inhibition of acid secretion by fat is not mediated by suppression of gastrin release.

5359 HISTAMINE-SENSITIVE ADENYLATE CYCLASE OF HUMAN GASTRIC MUCOSA. (Eng.) Simon, B.; Kather, H. (Medizinischen Universitatsklinik Heidelberg, Heidelberg, W. Germany). *Gastroenterology* 73(2):429-431; 1977.

The effects of histamine, prostaglandin E_2, sodium fluoride, and 5-guanylyl-imidodiphosphate [GMP(PNP)] on the adenylate cyclase system of human fundic gastric mucosa was investigated. This system responded to all activators. Half-maximal stimulation of enzyme activity was observed at a histamine concentration of 50 μM. Maximal stimulation (about 250%) occurred at a histamine concentration of 1 mM. The stimulatory effect of histamine was competitively inhibited by cimetidine (10 and 50 μM). The stimulatory effect of prostaglandin E_2 was dose-dependent over a concentration range of 0.1 μM-1 mM, exerting maximal effects at 0.3 mM. NaF and GMP(PNP), by inducing an about 3.5-fold increase of enzyme activity, were more potent in stimulating the human enzyme system than were histamine and prostaglandin E_2. Maximal stimulatory doses of prostaglandin E_2 and histamine had an additive effect on the adenylate cyclase activity from fundic gastric mucosa. This result implies that histamine acts on an individual adenylate cyclase system. The results suggest the existence of an adenylate cyclase system in human gastric mucosa coupled to histamine H_2-receptor site

5360 METHYLATION OF HISTAMINE IN THE GASTRIC MUCOSA. (Eng.) Maslinski, S.; Schippert, B.; Kovar, K. A.; Sewing, K. F. (Dept. Pharmacology, Univ. Tubingen, Tubingen, W. Germany). *Digestion* 15(6):497-505; 1977.

Methylation of histamine in the gastric mucosa of guinea pigs, cats, dogs, rats, and pigs was studied *in vitro* and *in vivo*. When gastric mucosal homogenates of these species were incubated with ^{14}C-histamine in the presence of S-adenosyl methionine, N^{τ}-methylhistamine was formed as the only methylated histamine derivative. Excessive concentration of N^{τ}-methylhistamine inhibited the formation of N^{τ}-methylhistamine. Pretreatment of guinea pigs with prednisolone (25 mg/kg, i.p., 4 days), aminoguanidine (250 mg/kg x 2), or pentagastrin (125 μg/kg x 3) neither influenced *in vitro* the formation of N^{τ}-methylhistamine significantly nor shifted the methylation reaction towards the side-chain. Pretreatment of guinea pigs with cimetidine (25 mg/kg x 3, i.p.) significantly enhanced the formation of N^{τ}-methylhistamine *in vitro*. In pooled samples of guinea pig gastric mucosa histamine and N^{τ}-methylhistamine were found. Under none of these circumstances was N^{α}-methyl- or N^{α},N^{α}-dimethylhistamine found. It is concluded that, in rat, guinea pig, cat, dog, and pig gastric mucosa, the formation of N^{τ}-methylhistamine is the only methylating pathway of histamine. In cases where other methylated histamine derivatives (N^{α}-methyl- and/or N^{α},N^{α}-dimethylhistamine) are found, they must originate in sources other than the gastric mucosa.

5361 EFFECT OF THE PROSTAGLANDIN PRECURSOR, ARACHIDONIC ACID, ON HISTAMINE STIMULATED GASTRIC SECRETION IN THE CONSCIOUS DOG, AND OBSERVATIONS ON THE EFFECT OF INHIBITING ENDOGENOUS PROSTAGLANDIN SYNTHESIS. (Eng.) Conolly, M. E.; Bieck, P. R.; Payne, N. A.; Adkins, B.; Oates, J. A. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12, England). *Gut* 18(6):429-437; 1977.

The effects of i.v. infusions of prostaglandin E_2 (PGE_2) and arachidonic acid (AA) on histamine-stimulated gastric secretion were studied in conscious dogs with either a simple gastric fistula or a denervated Heidenhain pouch. Both compounds produced a dose-related inhibition of acid secretion, though AA was 86.5 to 203.2 times less potent than PGE_2. The maximal effect of AA was not achieved until 20-40 min after the infusion had ceased, suggesting that AA has to undergo some kinetic or metabolic process before it can act. Eicosatetraynoic acid (ETYN) 1.0 μg/kg/min, an inhibitor of PG biosynthesis, almost totally abolished the antisecretory effect of AA up to 200 μg/kg/min. At 400 μg AA/kg/min, the antisecretory effect was reduced by about one-half. The effect of PGE_2 was not altered by ETYN. Furthermore, ETYN did not increase the response to histamine stimulation in control studies; this result suggests that prostaglandins are not involved in regulating gastric secretion in this model.

362 STIMULATION OF PROSTAGLANDIN OUTPUT FROM RAT STOMACH BY HYPERTONIC SOLUTIONS.

(Eng.) Assouline, G.; Leibson, V.; Danon, A. (Clinical Pharmacology Unit, Ben-Gurion Univ. of the Negev, Beer-Sheva, Israel). *Eur. J. Pharmacol.* 44 (3):271-273; 1977.

The effects of hypertonic solutions on the prostaglandin (PG) E output of a whole-cell preparation of rat stomach were investigated. In control experiments, the time course of PGE output indicated higher initial outputs, which then stabilized after 60 min at mean outputs of 2.5-2.9 ng/100 mg/30 min. Hypertonic sodium chloride or mannitol or urea buffers were added after 120 min. A 750 mOsm NaCl buffer produced 2.0- and 3.3-fold increases in PGE outputs at 150 and 180 min, resp., above the level observed at 120 min, while a 1,500 mOsm NaCl buffer stimulated PGE output 10.2- to 11.7-fold. PGE output was enhanced to a comparable degree with 1,500 mOsm hypertonic mannitol buffer (12.7 and 8.3-fold increases at 150 and 180 min, resp.), whereas the same osmolar concentration of urea was much less effective (2.0 and 1.3-fold stimulation). The osmolarity of the gastric contents may play a role in regulating gastric PG biosynthesis.

363 INHIBITION IN THE RAT OF GASTRIC ACID SECRETION AND CYCLIC AMP ANALOGS ACCUMULATION IN VITRO BY SOMATOSTATIN.

(Eng.) Lippmann, W. (Biochemical Pharmacology Dept., Ayerst Res. Lab., P.O. Box 6115, Montreal, Quebec H3C 3JI, Canada). *Experientia* 33(1):61-63; 1977.

The effects of somatostatin and its analogs on gastric acid secretion and on prostaglandin-induced pituitary cyclic AMP were investigated in unanesthetized male rats. Somatostatin (0.6 μmol/kg, s.c.) decreased the basal gastric acid output from 60 μEq/15 min to 10 μEq/15 min for a period of 15 min with maximal inhibition occurring by 30 min. Somatostatin (1 x 10^{-7} M) inhibited the adenohypophyseal cyclic AMP accumulation induced by prostaglandin E_2 by about 50%. At 0.6 μmol/kg, Di-Gly-somatostatin (Di-Gly-S), and Leu-di-Gly-S exhibited activities, with respect to the duration and degree of inhibition, similar to somatostatin (86 min, 71%). Leu-di-Gly-[descarboxy^{14}]-S was shorter in duration of action (41 min) while being as effective in degree of inhibition. [Des-Ala^{1}Gly^2][desamino^3][descarboxy^{14}]-S was shorter in duration of action than somatostatin (39 min versus 90 min) but exhibited a similar degree of inhibition (60% versus 59%); similar activities were exhibited by [Des-Ala^{1}Gly^2][acetyl^3][descarboxy^{14}]-S (43 min versus 74 min, 72% versus 75%). Each of the analogs was similar to somatostatin with respect to the maximal inhibitory effect and time in reaching this effect; the less active analog allowed a more rapid rate of return to control secretory levels than did somatostatin. At 1 x 10^{-7} M, di-Gly-, tri-Gly- and [Des-Ala^{1}Gly^2][acetyl^3][descarboxy^{14}]-S and [Des-Ala^{1}Gly^2][desamino^3][descarboxy^{14}]-S analogs showed similar inhibitory activity; the retro-enantio-derivative of the latter analog was ineffective even at 1 x 10^{-4} M as was [desamino^1][descarboxy^{14}]-retro-enantio-S. With the analogs examined, the gastrointestinal and pituitary receptors appear to exhibit generally similar recognition specificity with the differences within the gastrointestinal activities reflecting duration of availability rather than receptor affinity.

5364 EXPERIMENTAL STUDY ON THE INHIBITORY MECHANISM OF GASTRIC SECRETION: THE INHIBITORY EFFECT OF ELECTRICAL AUTONOMIC NERVE STIMULATION, AND ANTRAL AND DUODENAL ACIDIFICATION ON TETRAGASTRIN-STIMULATED GASTRIC SECRETION IN DOGS.

(Jpn.) Kondo, T. (Sch. Medicine, Tokushima Univ., Tokushima, Japan). *Shikake Acta Med.* 31(6):417-432; 1975.

The effects of electrical autonomic nerve stimulation (hepatic, celiac branches, and greater splanchnic nerve) and of antral and duodenal acidification on tetragastrin-stimulated gastric secretion were studied in 38 anesthetized dogs with total gastric fistula. Electrical stimulation of the hepatic nerves decreased acid secretion by 34.5% and pepsin secretion by 43.3%. Acid secretion was significantly decreased 42.5% by electrical stimulation of the celiac branches, and pepsin secretion was significantly increased 39.8%. Greater splanchnic nerve stimulation resulted in significant decreases in acid and pepsin secretion (50.3% and 54.2%, resp.). Antral acidification failed to inhibit gastric secretion, but duodenal acidification significantly decreased acid secretion 49.2% and pepsin secretion 46.4%. The hepatic, celiac branches, and greater splanchnic nerve have an inhibitory effect on gastric secretion.

5365 VAGAL INFLUENCES ON GASTRIC ACID SECRETION. EXPERIMENTAL STUDIES IN CATS.

(Eng.) Svensson, S. O. (Karolinska Institutet, Stockholm, Sweden). *Scand. J. Gastroenterol.* 11(40):1-34; 1976.

The effect of various stimulatory and inhibitory factors on gastric acid secretion was studied in cats to evaluate the physiological significance of such factors on oxyntic glands. The results are discussed in relation to six reference papers. Cats had either a vagally denervated fundic pouch (HP) to eliminate vagal influence on oxyntic glands or a vagally innervated mucosal septal fundic pouch. A dose-response relationship was found between the amount of food consumed and the HP acid response. The maximal postprandial acid response was 70% of the maximal HP response to pentagastrin (i.v., 0.25-128 μg/kg/hr), suggesting that feeding does not release enough gastrin to produce maximal stimulation of the oxyntic glands. A high correlation was noted between the HP acid secretion and the immunoreactive gastrin level in the serum of HP cats. Basal vagal tone and a threshold dose of a stable choline ester (methacholine, 15-30 μg/kg/hr) increased the sensitivity and secretory capacity of the oxyntic glands following stimulation with gastrin. A physiological increase of vagal activity above basal level by feeding was more effective than basal vagal tone in enhancing the acid response to a submaximal dose of gastrin. It is suggested that endogenous gastrin is the main stimulus of acid secretion in HP cats during the first postprandial hour and that a cholinergic mechanism is involved in postprandial gastrin release.

5366 GASTRIC ACID SECRETION IN GASTRIC FISTULA DOGS AFTER ANTRAL DENERVATION AND ANTRECTOMY.

(Eng.) Trout, H. H., III; Elashoff, J.; Harmon, J. W. (Walter Reed Army Medical Center, Washington, DC 20012). *Gastroenterology* 73(3): 492-494; 1977.

Studies were carried out in gastric fistula dogs to determine whether the increase in maximal histamine and gastrin-stimulated acid secretion seen after antrectomy can also be detected in the innervated *in situ* gastric remnant and whether it could be a consequence of vagal denervation of the duodenum during antrectomy. Dogs with gastric fistulae were tested with histamine and tetragastrin as a control study. The vagal nerve fibers to the antrum were divided, and the dogs underwent repeat testing. Finally, an antrectomy was performed and final dose-response data were collected. After antrectomy, there was an increased acid response to histamine ($p<0.05$) and tetragastrin (not significant). It is postulated that the vagal fibers innervating the antrum are probably not a factor in this increase. The fact that increased acid secretion is observed in the dog after antrectomy and that a decrease is known to occur in humans is a species difference and is not related to the pouch method of study used in earlier studies of the antrectomized dog.

5367 PARTICIPATION OF THE JEJUNUM AND ILEUM IN POSTPRANDIAL GASTRIC SECRETION IN MAN.

(Eng.) Clain, J. E.; Malagelada, J. R.; Go, V. L. W.; Summerskill, W. H. J. (Mayo Clinic, Rochester, MN 55901). *Gastroenterology* 73(2):211-214; 1977.

To determine the role of the small intestine in postprandial gastric secretory function, gastric functions were determined in six healthy subjects after diversion of intestinal chyme at the angle of Treitz and during normal digestion. A standard meal containing polyethylene glycol marker was given by gastric tube. The meal was diverted by means of an occlusive balloon. The chyme was entirely diverted by siphonage immediately proximal to the balloon. In control experiments, chyme was reinfused on the distal side of the balloon, and in the diversion experiments, saline was reinfused. Diversion of chyme decreased postprandial gastric secretory volume and acid output by approximately one-fourth; this was primarily evident during the first hour. The integrated 3-hr postprandial serum gastrin response after diversion (703 ± 199 pg) was not significantly different ($p>0.05$) from that of the controls (562 ± 133 pg). It is concluded that the small intestine contributes appreciably to the magnitude of gastric secretory responses to meals.

5368 CANINE GASTRIC ACID SECRETION AND BLOOD FLOW MEASUREMENT IN HEMORRHAGIC SHOCK.

(Eng.) Shirazi, S. S.; Mueller, T. M.; Hardy, B. M. (Univ. Iowa Hosp. and Clinic, Iowa City, IA 52242). *Gastroenterology* 73(1):75-78; 1977.

The effect of hemorrhagic shock on total and regiona gastric blood flow was investigated in five anesthetized and five conscious dogs; the effectiveness of retransfusion in restoring the blood flow to the stomach was also investigated. Gastric blood flow was measured with 15-μ labeled microspheres. Acid secretion and regional flow under control conditions (mean blood pressure [BP]=100 mm Hg), after 1 hr of hemorrhagic shock (mean BP=40 mm Hg), and 60 min after retransfusion of shed blood (mean BP= 100 mm Hg) were measured. The hydrogen ion secretion dropped significantly, from 0.63 ± 0.01 to 0.18 ± 0.02 mEq/hr in anesthetized dogs and from 2.1 ± 0.5 to 0.11 ± 0.01 mEq/hr in conscious dogs when shock was induced. Retransfusion of blood increased the rate of acid secretion in both groups the degree of increase was not significant in the anesthetized group. Fundic mucosal blood flow (FMBF) was 35 ± 1.9 ml/min/100 g tissue for the control period in anesthetized dogs and 94 ± 10 ml/min for conscious dogs. The flow dropped to 9 ± 1.8 ml/min in anesthetized dogs and to 23 ± 8 ml/min in conscious dogs with the induction of shock. The control FMBF was significantly higher in conscious dogs than in anesthetized dogs and significantly higher in conscious dogs during shock than during shock in anesthetized dogs ($p<0.05$). In anesthetized dogs, the drop in resting antral mucosa blood flow (AMBF), from 30 ± 5.1 to 15 ± 2 ml/min for the shock period, was less than occurred in the fundic mucosa, and the difference between FMBF and AMBF for the shock period was significant ($p<0.05$). Retransfusion of blood increased the flow rate in both groups but did not restore it to resting levels. AMBF of conscious dogs was significantly higher than FMBF after retransfusion. Muscularis blood flow for fundus and antrum dropped with the induction of shock, and retransfusion increased the flow to less than the resting level. The perfusion of fundic mucosa is more sensitive to hemorrhagic shock, which may explain the propensity of stress ulcers to be located in the fundu

5369 EFFECTS OF FUNDIC DISTENTION ON PENTAGASTRIN-STIMULATED GASTRIC ACID SECRETION IN MAN.

(Eng.) Grotzinger, U.; Bergegardh, S.; Olbe, L. (Kantonsspital, CH-4004 Basel, Switzerland *Gastroenterology* 73(3):447-452; 1977.

The acid secretory effect of combined stimulation by balloon distention of the fundus and body of the stomach and infusion of pentagastrin was studied in patients with duodenal ulcer (DU) and in healthy subjects. In eight nonoperated DU patients and in five DU patients subjected to proximal gastric vagotomy, low grade fundic distention moderately enhanced the acid output evoked by a threshold dose of pentagastrin (0.5 or 1.6 μg/hr; basal, pentagastrin-stimulated, and pentagastrin + distention-stimulated secretion 3.17 ± 0.57, 4.45 ± 0.66, and 5.81 ± 0.81 mmol/15 min, resp.). Fundic distention with a balloon volume eliciting a maximal acid response to distention either left unchanged or suppressed the maximal acid secretory rate produced by pentagastrin in seven nonoperated and six vagotomized DU patients and in five healthy subjects. The heterogeneous secretory effects of maximal stimulus combination suggest that fundic distention has a complex action on acid secretion eliciting a hitherto unknown inhibitory effect as well as a cholinergic activation of the parietal cell area. This complex action may explain the failure of fundic distention to augment markedly the action of pentagastrin in this study.

5370 EXPERIMENTAL STUDY ON GASTRIC SECRETION AFTER MASSIVE SMALL BOWEL RESECTION. (Jpn.) Kano, Y. (Sch. Medicine, Tokushima Univ., Tokushima, Japan). *Shikoki Acta Med.* 32(1):45-60; 1976.

Gastric secretion was studied in Heidenhain pouch dogs with either a two-thirds proximal or two-thirds distal small bowel resection. The dogs with proximal bowel resection had a more prominent decrease in body weight than did those with distal resection. The basal fasting levels of pouch acid secretion and of serum gastrin were similar in the two groups. The volume output, acidity, and total acid output increased markedly 2 hr after feeding in the dogs with proximal bowel resection. During the 6 hr following feeding, the volume output increased by an average of 138%, and the total acid output increased an average of 268%. Pouch secretion in the animals with distal resection was similar to that in controls without resection. The serum gastrin level after feeding increased with time in the dogs with proximal resection and decreased with time in those with distal resection. Pouch secretion and serum gastrin levels were similar in dogs with proximal resection alone and with proximal resection with vagotomy. The numbers of parietal cells, gastric epithelial cells, and villi of the residual small intestine increased in the animals with increased gastrin levels.

SECRETION AND METABOLISM

Pancreas

5385 SECRETION OF LABELLED PROTEINS BY THE ISOLATED DOG PANCREAS IN THE RESPONSE TO SECRETIN AND CHOLECYSTOKININ. (Eng.) Laval, J.; Frexinos, J.; Laval, J. P.; Ribet, A. (Groupe de Recherche de Biologie et Pathologie Digestive, INSERM, U-151, CHU Rangueil, Chemin du Vallon, Bat. L3, 31400 Toulouse, France). *Biomedicine* 26(1):65-70; 1977.

The effects of secretin alone (10 clinical U/hr) and secretin (same dose) plus cholecystokinin-pancreozymin (CCK-PZ, 10 Ivy U/hr) on the secretion of radioactively labeled proteins in the pancreatic juice from isolated dog pancreas perfused *ex vivo* with whole heparinized oxygenated blood were compared. The average values for protein output showed the same pattern for both types of stimulation. After a washing out period, protein outputs were constant from about the 30th min onwards in the experiment. However, the average protein output was two- to threefold higher under the influence of CCK-PZ plus secretin (3-4 mg/min) than with the secretin alone (1-2 mg/min). Both types of stimulation caused an increase in pancreatic secretory flow rate 10 min after the start of infusion, with the secretory flow rates leveling out 20-30 min later and diminishing after the 60th min. With both types of stimulation, radiolabeled proteins appeared in the pancreatic juice about 20-25 min after the injection of leucine tracer. The secretion of labeled proteins, which reflected the biosynthesis, transport, and secretion of the enzymes, increased linearly until the 55th min after tracer injection, corresponding to the plateau of the protein output. The average value of maximum radioactivity was three times higher under the influence of CCK-PZ plus secretin than with secretin alone. The time course of protein specific radioactivity indicated that during the 50 min following tracer injection both treatments had an identical action. Afterwards, CCK-PZ plus secretin treatment produced a maximum in protein specific radioactivity in the pancreatic juice that was lower and occurred later than with secretin alone. It is concluded that CCK-PZ and perhaps secretin act on the synthesis and transport of the secretory proteins of the exocrine pancreas.

5386 PLASMA SECRETIN AND PANCREATIC BICARBONAT RESPONSE TO EXOGENOUS SECRETIN IN MAN. (Eng.) Hacki, W. H.; Bloom, S. R.; Mitznegg, P.; Domschke, W.; Domschke, S.; Belohlavek, D.; *et al.* (Royal Postgraduate Medical Sch., London W12 OHS, England). *Gut* 18(3):191-195; 1977.

To help clarify the physiological role of secretin, the dose response of duodenal bicarbonate productio during synthetic porcine secretin infusions was studied in six healthy subjects and related to plasma secretin immunoreactivity. Secretin was infused in each subject at four different doses (from 0.1-2.7 clinical U/kg/hr), each infusion lasting 60 min. The mean maximal bicarbonate secretion was 33 ± 4 mEq/hr. The ratio of the mean incremental plasma secretin levels at the different infusion rates were 1:2.8:10.0:30.5, reflecting very closely the grading of the infusion secretin content. At the end of the last infusion, there was a rapid fall in the plasma secretin to only 8% of the maximal increment after 10 min. The half-life of secretin was estimated at approximately 2.8 min. The secretin plasma level for half-maximal bicarbonate response was estimated to be 22 pmol/l. As this level is reported to be achieved by intraduodenal acidification in man, it is concluded that secretin may play a part in the control of duodenal pH.

5387 PANCREATIC BICARBONATE, SERUM GASTRIN, AND SECRETIN RESPONSES TO MEALS VARYING IN pH. (Eng.) Llanos, O. L.; Konturek, S. J.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Physiol.* 233(1):E41-E46; 1977.

To investigate the role of secretin in the postprandial bicarbonate response of the pancreas, secretin and bicarbonate secretion were studied in dog

h gastric and pancreatic fistulas after exo-
ous and endogenous acidification of meal. A
er extract meal at various pH levels was intro-
ed into the stomach and kept at the preselected
by intragastric titration. Gastric acid, pan-
atic bicarbonate, serum gastrin, and plasma
retin were measured. The meal at pH 7 produced
increase of gastrin levels 230% above basal
a gastric acid output of 16.9 mEq/30 min, com-
ed to a basal level of 0.8 mEq/min. Acidifica-
n of the meal evoked a pH-dependent reduction of
trin and gastric acid secretion, a pH-dependent
vation of pancreatic bicarbonate, and signifi-
t elevation of secretin at pH 3 (43% above basal)
at pH 2 (80% above basal). Postprandial endo-
ous acidification of a meal, without intragas-
c titration, also provoked significant release
secretin. Maximal pancreatic bicarbonate secre-
n in response to exogenous secretin was augmented
by the addition of a liver extract meal at pH
It is concluded that, in dogs with pancreatic
tulas, a meal exogenously or endogenously (post-
ndial) acidified is capable of stimulating the
ease of secretin in immunoassayable amounts.
normal pancreatic bicarbonate response to food
depend partially upon potentiation of the
retin effect by other neurohumoral stimuli.

8 VASOACTIVE INTESTINAL PEPTIDE: A SECRETIN-LIKE PARTIAL AGONIST FOR PANCREATIC SECRE-
N IN MAN. (Eng.) Domschke, S.; Domschke, W.;
ch, W.; Konturek, S. J.; Sprugel, W.; Mitznegg,
et al. (Dept. Medicine, Univ. Erlangen-Nurnberg,
nkenhausstrasse 12, D-8520 Erlangen, W. Germany).
troenterology 73(3):478-480; 1977.

responses of pancreatic volume flow and bicar-
ate output to i.v. vasoactive intestinal peptide
P, 0.8-3.2 μg/kg/hr) were compared to those ob-
ned with synthetic secretin (32.2-129 ng/kg/hr)
five healthy volunteers. Pure pancreatic juice
obtained by endoscopic cannulation of the main
creatic duct. The mean observed maximal response
secretin-stimulated juice flow was 248 ± 7 μl/kg/
in, whereas the observed maximal response for VIP-
ked juice flow was 48 ± 6 μl/kg/5 min. The ob-
ved maximal secretin-induced bicarbonate output
30 ± 2 μEq/kg/5 min, and the maximal VIP-related
sponse was 4.3 ± 0.9 μEq/kg/5 min. In addition
low efficacy, the high dose requirements and side-
fects (significant rise in pulse rate and cutaneous
shing at 3.2 μg/kg/hr) argue against a major
ysiological role of VIP as a hormonal stimulant
human pancreatic bicarbonate secretion.

39 EFFECT OF VINBLASTINE ON PANCREATIC EN-ZYMES SECRETION INDUCED BY CYCLIC NUCLEO-
DE DERIVATIVES. (Eng.) Stock, C.; Launay, J.
; Grenier, J. F.; Bauduin, H. (Unite 61 de
INSERM de Biophysiopathologie de l'Intestin,
57200 Strasbourg, France). *Experientia* 33(8):
56-1068; 1977.

investigate the possible participation of micro-
bules in the secretory response of the pancreas
cyclic nucleotide derivatives, the effects of
the mitotic spindle-inhibitor, vinblastine, on both the function and the ultrastructure of the acinar cell were examined. Vinblastine (5×10^{-5} M) induced the disappearance of microtubules accompanied by the appearance of paracrystalline deposits in the cytoplasm of rat acinar cells. Increased amylase and lipase release by the *in vitro* pancreas treated with 1 mM dibutyryl cyclic AMP alone or in combination with 5×10^{-5} M vinblastine was confirmed by the observation of numerous pictures of exocytosis at the apex of the acinar cells as well as the presence of a dense secretory material in the acinar lumina. Dibutyryl cyclic guanosine monophosphate (1 mM) and vinblastine did not significantly affect the spontaneous release of enzymes, either alone or in combination. Dibutyryl cyclic guanosine monophosphate alone or associated with vinblastine did not modify the secretory response to dibutyryl cyclic AMP. The results support the previous suggestion that dibutyryl cyclic AMP stimulates enzyme release from the pancreas through a direct interaction with the acinar cell.

5390 THE EFFECT OF HYOSCINE-n-BUTYLBROMIDE ON EXOCRINE PANCREATIC SECRETION. (Eng.)

Odes, H. S.; Helman, C. A.; Barbezat, G. O.; Bank, S. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 52(1):17-19; 1977.

The effect of hyoscine-*N*-butylbromide on secretin-stimulated pancreatic secretion was studied in 10 men who were being evaluated for possible pancreatic disease. Each patient underwent two 80-min pancreatic function tests in tandem, the tests being separated by an interval of 30 min. Secretin (2 U/kg, i.v.) was administered before each test, and cholecystokinin-pancreozymin (CCK-PZ, 1.5 U/kg) was administered at the end of the first hour. Hyoscine-*N*-butylbromide (40 mg, i.v.) was administered before the second test. The volume output after secretin stimulation was not affected by hyoscine-*N*-butylbromide, but a significant increase in the mean bicarbonate concentration occurred (72 ± 6 mEq/l before, 92 ± 5 mEq/l after, $p<0.01$). There were also significant reductions in total protein (10.9 ± 0.9 versus 4.2 ± 0.5 mg/ml, $p<0.001$), trypsin (2.2 ± 0.2 versus 1.1 ± 0.1 benzylarginine ethyl ester U x 10^3/ml, $p<0.001$), and amylase (4.8 ± 0.9 versus 2.4 ± 0.4 U x 10^3/ml, $p<0.01$). Hyoscine-*N*-butylbromide produced no significant changes in CCK-PZ-stimulated volume output and bicarbonate, protein, trypsin, and amylase concentrations.
The use of hyoscine-*N*-butylbromide as a duodenal relaxant before the collection of pancreatic juice during retrograde endoscopic pancreatography may lead to a low estimation of secretin-stimulated secretion.

5391 EFFECTS OF CHRONIC ETHANOL CONSUMPTION ON PANCREATIC RESPONSE TO CENTRAL VAGAL STIMULATION BY 2-DEOXY-D-GLUCOSE IN THE RAT. (Eng.)

Chariot, J.; Roze, C.; de La Tour, J.; Souchard, M.; Hollande, E.; Vaille, C.; Debray, C. (Hopital Bichat, 170 bd Ney, F-75877 Paris Cedex 18, France). *Digestion* 15(5):425-437; 1977.

The effects of chronic ethanol consumption on the pancreatic response to central vagal stimulation by 2-deoxy-*D*-glucose (2DG; 75 or 225 mg/kg, i.v.) were investigated in male Wistar rats given a 20% ethanol solution in drinking water *ad libitum* for 3 months. Basal sodium secretion (-30%, $p<0.001$), bicarbonate (-35%, $p<0.001$), and total protein (-35%, $p<0.001$) were depressed in alcoholic versus control rats. Pancreatic response was identical in both groups with the smaller dose of 2DG, dose related in controls, and identical for both doses in alcohol-fed rats. The response was thus significantly smaller in alcohol-fed rats than in controls for the larger dose of 2DG ($p<0.01$). Pancreatic concentration and contents of amylase, trypsinogen, chymotrypsinogen and lipase were all decreased 40-60% in alcoholic versus control rats ($p<0.001$). These results are consistent with the hypothesis of functional modifications in pancreatic cholinergic innervation in alcohol-fed rats.

5392 EXOCRINE PANCREATIC SECRETION INDUCED BY INGESTION OF A MEAL: STUDIES IN PURE PANCREATIC JUICE OBTAINED FROM EXTERNAL PANCREATIC FISTULAS. (Eng.) Ribera, M. T.; Leitao, C. N. (Hosp. de San Pablo, Barcelona 13, Spain). *Am. J. Gastroenterol.* 67(2):131-134; 1977.

5393 SUPPRESSION OF THE EXOCRINE FUNCTION AS A AID TO OF [sic] SEGMENTAL PANCREATIC TRANSPLANTATION IN DOGS. (Eng.) Dubernard, J. M.; Traeger, J.; Neyra, P. (Hopital E. Herriot, Place d'Arsonval, 69374 Lyon Cedex 2, France). *Biomedicine* 27(4):172-174; 1977.

5394 IN-SITU-ISOLATED PERFUSED RAT PANCREAS: A NEW METHOD FOR PHARMACOLOGICAL STUDIES OF THE EXOCRINE PANCREAS. (Eng.) Tournut, R.; Estival, A.; Vaysse, N.; Pascal, J. P.; Ribet, A. (INSERM U-151, Batiment L3, CHU Rangueil, Chemin du Vallon, F-31400 Toulouse, France). *Digestion* 15(4):329-337; 1977.

SECRETION AND METABOLISM

Hepatobiliary Tract

5395 PRELIMINARY TRIAL OF A NEW TEST FOR THE ASSESSMENT OF LIVER CELL FUNCTION: THE TMB TEST. (Fre.) Rousselet, F.; Charbonnier, A.; Fredj, G.; Nepveux, P.; Fluteau, G.; Cachin, M. (Centre d'Enseignement Pharmaceutique, Universite Rene Descartes, 4, avenue de l'Observatoire, 75006 Paris, France). *Sem. Hop. Paris* 53(18/19):1049-1051; 1977.

Liver cell function was assessed by administration of trimethoxy-1,3,5-benzene (TMB, 400 mg, p.o.) and measurement of its metabolites, mainly dimethoxy-1, 3-hydroxy-5-benzene (DMHB), excreted in the urine after 0-3 hr (a fraction), 3-7 hr (b fraction), and 7-24 hr (c fraction). Values were obtained from 17 healthy subjects, followed by a blind study of 48 patients with various digestive illnesses. Hepatic disorders showed a delay or diminution in the total excretion of DMHB, with the values for the a fraction being most affected. The test was positive in 31/32 patients with previously diagnosed liver disease. The results were significant for liver cirrhosis ($p<0.00001$), alcoholism ($p<0.001$), liver disorders ($p<0.0000001$), and secondary tumors of the liver ($p<0.05$). Abnormal results were also obtained in 11 other patients whose routine liver function tests were normal, but whose diseases were concomitant with mild liver disturbances. The TMB technique promises to be a sensitive test for subclinical and laboratory-negative liver failure.

5396 STUDIES ON METABOLISM OF ANTIBIOTICS. I. BIOTRANSFORMATION OF CEPHALOTHIN (CET) IN PATIENTS AND ANIMALS WITH LIVER IMPAIRMENT. (Jpn.) Komatsu, T. (Hokkaido Univ. Sch. Medicine, Sapporo, Japan). *Chemotherapy* 25(4):555-564; 1977.

The metabolism of cephalothin (CET) was studied in humans and rats with and without liver disease. Thin layer chromatography and autoradiography were used to study the transformation of CET to its main metabolite, desacetyl-CET (DA-CET). Acute liver injury was produced in rats by the administration of CCl_4 for 3 days, and chronic injury (liver cirrhosis) was induced by administration for 5 months. Untreated controls and the rats with liver injury received an i.v. injection of CET (100 µg/kg). In controls, the biliary excretion of DA-CET decreased from 1,610 µg/ml at 1 hr after CET injection to 346.7, 56.0, and 12.5 µg/ml at 2, 3, and 4 hr, resp. In rats with acute liver injury, the respective values were 1,342.5, 72.0, 5.4, and 7.1 µg/ml, and in rats with chronic liver injury, they were 400, 135, 30.3, and 10.8 µg/ml. Four hours after injection, the DA-CET levels in the urine were 25,000, 19,500, and 10,300 µg/ml in the control the rats with acute injury, and the rats with chronic injury, resp. The activity of CET-desacetylase was found to be highest in the cytosol fraction of liver homogenates of control rats, but the activity in this fraction decreased in the rats with liver

jury, particularly in those with liver cirrhosis.
rum SGOT, SGPT, alkaline phosphatase, and γ-globu-
n levels were increased and aspirin esterase and
enylacetate esterase levels were decreased in the
ts with liver injury. Paranitrophenylacetate
terase activity was highest in the lysosomal and
tochondrial fractions, and both aspirin esterase
d phenylacetate esterase activities were highest
the microsomal fraction in the controls; these
tivities decreased in rats with liver injury. The
ver diseases in the human subjects included liver
rrhosis, chronic hepatitis, fatty liver, and obstruc-
ve jaundice. The ratio of CET/DA-CET in 2-hr
ine collections and the urinary recovery of CET
hr after CET administration were not significantly
fferent in the patients and in controls without
ver impairment. There was no correlation between
e ratio of CET/DA-CET and parameters of liver
nction.

97 STUDIES ON METABOLISM OF ANTIBIOTICS. II.
BIOTRANSFORMATION OF RIFAMPICIN (RFP) IN
TIENTS AND ANIMALS WITH LIVER IMPAIRMENT. (Jpn.)
matsu, T. (Hokkaido Univ. Sch. Medicine, Sapporo,
pan). *Chemotherapy* 25(4):565-574; 1977.

e metabolism of rifampicin (RFP) was studied in
tients with liver diseases (cirrhosis, chronic
patitis, fatty liver, obstructive jaundice, chole-
thiasis, and postcholecystectomy syndrome) and
guinea pigs with CCl_4-induced liver injury. The
imals received 0.1 ml of CCl_4, i.m. When RFP was
ministered p.o. (30 mg/kg), biliary and urinary
cretion of both RFP and its main metabolite, des-
etyl-RFP (DA-RFP), decreased to a greater extent
an in control animals without liver injury. The
P levels in the bile 1, 2, 3, and 4 hr after
ministration were 6.02, 13.34, 16.04, and 14.37
/ml, resp., in controls and 0.80, 3.71, 4.54, and
89 μg/ml in CCl_4-treated animals; the level in
e urine 4 hr after administration was 0.79 μg/ml
controls and 0 in the CCl_4-treated animals. The
-RFP levels in the bile of controls were 1.28,
65, 4.85, and 5.98 μg/ml at 1, 2, 3, and 4 hr,
sp., and 0, 0, 0, and 2.42 μg/ml in the CCl_4-treated
imals, resp.; there was no detectable DA-RFP in
e urine after 4 hr and the level in controls was
12 μg/ml. When RFP (2 mg/kg) was administered
v., only DA-RFP excretion in the urine and bile
creased in comparison with controls. In patients
th liver disease and in controls, the ratios of
P/DA-RFP in the urine 6 hr after the p.o. admin-
stration of 450 mg of RFP were similar. No posi-
ve correlations were found between the ratio of
P/DA-RFP and liver function tests.

98 THE MODE OF ACTION OF ALCOHOL ON THE HEP-
ATIC MICROSOMAL BIOTRANSFORMATION OF XENO-
IOTICS. (Fre.) Joly, J. G. (Hopital Saint-Luc, 1058.
e St.-Denis, Montreal, Quebec H2X 3J4, Canada).
ion Med. Can. 106(5):626-630; 1977.

ronic alcoholism is associated with cross toler-
nce between certain drugs, such as meprobamate,
d ethanol, with an increased tolerance to ethanol and with the potentiation of the action of some drugs, particularly sedatives, during inebriation. The first two phenomena are adaptive changes that result in a more rapid clearance of the exogenous substances. Electron microscopy has shown that the accelerated metabolic rate is due to the proliferation of the smooth endoplasmic reticulum of hepatocytes. This is accompanied by an increase in the levels of cytochrome P-450, NADPH-cytochrome P-450 reductase, and phospholipids. Alcoholism has been shown to lead to the appearance of a specific microsomal ethanol oxidizing system. Finally, when alcohol is present in the body, it slows down the metabolism of psychoactive drugs by competing for similar substrates, thereby lengthening the effect of these drugs.

5399 ORGAN CULTURE OF POSTNATAL RAT LIVER: EFFECTS OF ETHANOL ON LIPID METABOLISM.
(Eng.) Konrad, K. D.; Reed, G. B. (Cleveland Metropolitan General Hosp., 3395 Scranton Rd., Cleveland, OH 44109). *Exp. Mol. Pathol.* 26(3):425-433; 1977.

Organ culture explants of 3- to 5-day-old postnatal rat livers were used to examine the effect of ethanol on *in vitro* hepatocyte lipid metabolism. The livers were incubated with 1.0% ethanol (173 mM) for 6 hr. Lipogenesis, as measured by ^{14}C-acetate incorporation into explant lipids, and fatty acid esterification, measured by ^{14}C-palmitate incorporation into triglycerides, were both increased by ethanol administration; 1-^{14}C-palmitate incorporation was increased from 3,844 ± 188 to 1,905 ± 101 disintegrations per min (dpm) of $^{14}CO_2$/mg protein ($p<0.05$), and 1-^{14}C-acetate was increased from 123,422 ± 8,121 to 30,974 ± 3,689 dpm/mg ($p<0.005$). Production of $^{14}CO_2$ by the explants from ^{14}C-palmitate, ^{14}C-acetate, and ^{14}C-glucose was decreased following incubation with ethanol. Ethanol did not affect the release of labeled lipids from the explants into the media. Increases in the explant lactate pyruvate ratio during incubation with ethanol and incorporation of ^{14}C-ethanol into fatty acids indicated that the explants were oxidizing ethanol to acetate. Explant viability, as judged by ^{3}H-leucine incorporation into cellular protein and morphologic appearance by light and electron microscopy, was unaffected by incubation with 1.0% ethanol for up to 24 hr. Despite apparently increased lipogenesis and decreased fatty acid oxidation by the explants during ethanol administration, no statistically significant ethanol-induced increases in explant triglyceride or fatty acid concentration were found, unless the explants were incubated with media supplemented to 25% serum as an exogenous lipid source. These results indicate that acute hepatic explant lipid accumulation during ethanol administration is due primarily to deposition of exogenous lipids, with increased lipogenesis contributing only minimally to the increased deposition of lipids.

5400 ADULT RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE: ULTRASTRUCTURAL CHARACTERISTICS OF INTERCELLULAR CONTACTS AND CELL MEMBRANE DIFFERENTIATIONS. (Eng.) Wanson, J. C.; Drochmans, P.; Mosselmans, R.; Ronveaux, M. F. (Laboratoire de

Cytologie, Universite Libre de Bruxelles, 1000 Bruxelles, Belgium). *J. Cell. Biol.* 74(3):858-877; 1977.

The ultrastructural characteristics of the process of hepatocyte aggregation were analyzed under well-defined conditions of isolation and cell culture. Primary monolayer cultures were obtained in 60-mm petri dishes by incubating 3 x 10^6 isolated hepatocytes at 37 C in Dulbecco's medium supplemented with 17% fetal calf serum. Within 4 hr of plating, the isolated spherical cells were found to adhere to the plastic surface, to establish their first contacts by numerous intertwined microvilli, and to form new hemidesmosomes. After 12 hr of culture, wide branched trabeculae of flattened polyhedral cells extended in all directions. Finally, after 24 hr of culture, bile canaliculi were reconstituted, and a biliary polarity was recovered. The Golgi elements, which were scattered throughout the cytoplasm in the isolated cells, were reassembled in front of the newly formed bile canaliculi, symmetrically in the adjacent cells; lysosomes were concentrated in that region, and microtubules reappeared. Concomitantly, plasma membrane differentiations, namely desmosomes and tight junctions, developed. Tight junctions sealing the bile ducts constituted a barrier to the passage of ruthenium red and horseradish peroxidase. *De novo* formation of these junctions was studied by the freeze-etching technique. Ten-nanometer particles composed a network of anastomosed linear arrays in the vicinity of the bile canaliculi; in the next step of differentiation, the particles fused, formed short ridged segments, and finally formed continuous branched smooth strands, characteristic of the mature tight junction.

5401 IN VITRO SPECTRAL ALTERATION OF HEPATIC CYTOCHROME P-450 BY EXPERIMENTAL DRUG INJURY. (Eng.) Willson, R. A.; Hart, F. E. (Harborview Medical Center, 325 9th Ave., Seattle, WA 98104). *Res. Commun. Chem. Pathol. Pharmacol.* 17 (4):605-621; 1977.

Hepatic microsomes from normal and phenobarbital (75 mg/kg)-treated rats were incubated *in vitro* with dimethyl sulfoxide (DMSO), dimethyl formamide (DMF), or Triton X-100 to assess the effects of these solvents on cytochrome P-450 content. Incubations were carried out in the presence and absence of an NADPH generating system. Dose-response curves of DMSO, DMF, and Triton X-100 revealed that cytochrome P-450 content decreased with increasing concentrations of each solvent, when compared with a phosphate buffer. When acetaminophen (0.036 M) was added to the phosphate buffer or to the DMSO, there was no change in the cytochrome P-450 content when compared with their respective controls. However, at 0.14 M acetaminophen or greater, there was a significant decrease in cytochrome P-450 content, attendant with a prominent spectral peak at 420 nm. To ascertain whether nucleophilic compounds (i.e., glutathione, cysteamine, methionine, and cysteine) would prevent these spectral changes, they were investigated both *in vivo* and *in vitro*. None prevented the decrease in cytochrome P-450 content or the presence of the spectral peak at 420 nm. These studies indicate that solvents alone may cause a diminished cytochrome P-450 content and this may be amplified in phenobarbital-induced microsomes. High concentrations of acetaminophen caused a large decrease of the cytochrome P-450 content than did the DMSO alone, and this was more pronounced in the induced microsomes. Since addition of nucleophilic compounds did not alter these spectral changes, the mechanism of the acetaminophen-associated change in cytochrome P-450 content is unclear.

5402 CONNECTIVE TISSUE FIBERS IN THE LIVER OF SQUIRREL, AFTER CARBON TETRACHLORIDE POISONING. A HISTOCHEMICAL STUDY. (Eng.) Rana, S. V. S. (Dept. Zoology, D.A.V. Coll., Muzaffarnagar, India). *Anat. Anz.* 141(2):126-129; 1977.

Connective tissue fibrils were studied histochemically in the carbon tetrachloride-damaged livers of ground squirrels. The experimental animals received CCl_4 (0.0037 ml) i.p. on alternate days for 1 month, while controls received olive oil (0.5 ml). CCl_4 treatment resulted in the formation of "balloon" cells, which had a clear cytoplasm and a retracted nucleus. Rings of elastin were found within these cells and in no other area, whil elastin was found exclusively in the blood vessels in normal liver. After prolonged CCl_4 treatment, no reticulin fibers were stained. Thick bundles of collagen covered the damaged liver lobule, while only negligible amounts of collagen were scattered throughout the normal liver.

5403 THE METABOLIC FATE OF n-ACETYL-D-[1-^{14}C]-GALACTOSAMINE IN ISOLATED PERFUSED RAT LIVER. (Eng.) MacNicoll, A. D.; Wusteman, F. S.; Powell, G. M.; Curtis, C. G. (Dept. Biochemistry, Univ. Coll., P.O. Box 78, Cardiff CF1 1XL, Wales). *Biochem. Soc. Trans.* 5(2):442-443; 1977.

In an attempt to identify the major route(s) for th re-utilization of monosaccharides, the metabolic fa of *N*-acetyl-D-[1-^{14}C]galactosamine was studied in the isolated perfused rat liver. The liver was perfused with homologous heparinized blood (100 ml) containing *N*-acetyl-D-[1-^{14}C]galactosamine (20 µCi 103 µg). After 6 hr, approximately 50% of the administered galactosamine was utilized by the liver for glycoprotein synthesis. These glycoproteins were secreted into plasma. The radioactive label was present predominantly in sialic acid and glucosamine (either free of *N*-acetylated). It appears that the epimerization step is a major event in the utilization of *N*-acetylgalactosamine in the isolate perfused rat liver.

5404 THE ROLE OF THE LIVER IN GLUCAGON METABOLISM. (Eng.) Jaspan, J. B.; Huen, A. H. J.; Moreley, C. G.; Moossa, R.; Rubenstein, A. H. (Dept. Medicine, Univ. Chicago, Chicago, IL 60637). *J. Clin. Invest.* 60(2):421-428; 1977.

To study the role of the liver in glucagon metabolism, total plasma immunoreactive pancreatic glucagon (IRG) was measured in samples taken simul-

aneously from the proximal portal vein and super-
ior vena cava of 26 healthy Sprague-Dawley rats.
he portal-peripheral ratio of IRG was 2.80 ± 0.25,
he portal-peripheral difference was 124 ± 15 pg/ml,
nd percent extraction was 58 ± 3. Gel filtration
f paired portal and peripheral vein samples showed
hat reduction in the 3,500-dalton IRG component
glucagon) in peripheral samples accounted for
lmost all the differences, there being minimal and
nconsistent changes in the high molecular weight
>40,000) fraction. The portal-peripheral ratio of
he 3,500-dalton glucagon was 5.24 ± 1.10, the
ortal-peripheral difference 130 ± 33 pg/ml, and
he percentage extraction 81 ± 5. To study the
ranshepatic differences in the 9,000-dalton "pro-
lucagon-like" material, the experiment was re-
eated in nine rats 24 hr after bilateral nephrec-
omy. The portal-peripheral ratio for plasma IRG
n these rats was 1.48 ± 0.12, the portal-peripheral
ifference 140 ± 29 pg/ml, and percentage extraction
8 ± 5. Gel filtration revealed no consistent
ifferences between portal and peripheral concen-
rations of the 9,000- and >40,000-dalton components,
hich comprised 40% and 13%, resp., of the mean IRG
evel of 492 ± 35 pg/ml. In contrast, there were
arked differences between portal and peripheral
evels of the 3,500-dalton component; the ratio
eing 3.42 ± 0.63; the portal-peripheral difference,
82 ± 32 pg/ml; and percentage extraction 64 ± 5.
imilar studies in a healthy dog, in which species
here are significant circulating levels of the
,000 dalton IRG component, confirmed the selective
epatic extraction of the 3,500-dalton fraction.

405 THE EFFECT OF AGE ON PROTEIN SYNTHESIS BY ISOLATED LIVER PARENCHYMAL CELLS.

(Eng.)
an Bezooijen, C. F. A.; Grell, T.; Knook, D. L.
Inst. Experimental Gerontology TNO, 151 Lange Klei-
eg, Rijswijk, Netherlands). *Mech. Ageing Dev.*
(4):293-304; 1977.

o investigate the effect of age on hepatic protein
ynthesis, the protein synthesizing capacity of
iver parenchymal cells isolated from 3-, 12-, 24-,
1-, and 36-month-old rats was determined by the in-
orporation of ^{14}C-leucine. Conditions for optimum
rotein synthesis included the use of an enriched
edium (modified Waymouth's MB 752/1) and cell sus-
ension concentrations ranging from 0.25 to 4 x 10^6
ells/ml medium. The cells were incubated with a
ose of 6 μmol leucine/ml medium for 2 hr at 37 C
nder an atmosphere of 95% O_2 and 5% CO_2. With par-
nchymal cells isolated from 3-month-old rats, a leu-
ine incorporation rate of 14.4 nmol leucine/hr/10^6
ells was found. The capacity of the parenchymal
ells to synthesize protein decreased between 3 and
2 months, remained constant between 12 and 24 months,
nd increased between 24 and 36 months. Degradation
f newly synthesized proteins or reutilization of
^{4}C-leucine did not occur during the incubation per-
od. The ratio between albumin and total protein
ynthesis as a function of age was determined. This
atio did not change between 3 and 24 months, but
here was a significant increase between 24 and 36
onths. The increase in total protein synthesis in
ate age may be due to a compensation by the liver for a more pronounced proteinuria, increased proteolysis, or an accumulation of "altered" proteins.

5406 FASTER SYNTHESIS AND SLOWER DEGRADATION OF LIVER PROTEIN DURING DEVELOPMENTAL GROWTH.

(Eng.) Conde, R. D.; Scornik, O. A. (Departamento de Quimica Biologica, Universidad de Buenos Aires, Buenos Aires, Argentina). *Biochem. J.* 166(1):115-121; 1977.

The liver protein gain during the early stages of postnatal development was studied *in vivo* in 4-day-old mice. At this age, liver protein accumulated at a rate of 18% per day. Synthesis was measured after the injection of massive amounts of radioactive leucine (0.01 μCi/μmol). Degradation was estimated as the balance between synthesis and accumulation of stable liver proteins, or from the disappearance of radioactivity from liver protein previously labeled by the administration of NaH-$^{14}CO_3$. The neonatal livers synthesized 39% as much protein per unit time and unit mass as adult tissue, which was accounted for by a higher ribosome concentration (synthesis/mg RNA was the same). These livers retained 39% of the newly synthesized protein as stable liver components (compared with 48% in adult mice) and degraded protein at 56% of the rate in the adult liver. This lower rate of degradation is quantitatively the most significant difference between the growing and non-growing liver.

5407 ISOLATION OF A NON-THIONEIN COPPER-BINDING PROTEIN FROM LIVER OF COPPER-INJECTED RATS.

(Eng.) Irons, R. D.; Smith, J. C. (Chemical Industry Inst. Toxicology, P.O. Box 12137, Research Triangle Park, NC 27709). *Chem. Biol. Interact.* 18(1): 83-89; 1977.

A low molecular weight, non-thionein, Cu-binding protein was isolated from rat liver and characterized. The protein was isolated following chronic administration of $Cu(NO_3)_2$ using a combination of Sephadex G-75 and Sephadex DEAE A-25 chromatography. The protein did not bind to fully equilibrated Sephadex DEAE, which formed the basis of the isolation procedure. The final protein preparation was found to be homogeneous by a variety of electrophoretic techniques and was distinguished from metallothionein on the basis of its behavior on ion exchange and electrophoretic systems, spectral properties, amino acid composition, and metal content. It contained 6.8% cysteine and was found to bind Cu in a ratio of 1.5:1 based on a molecular weight of 11,000. These results confirm the necessity of using techniques other than gel filtration alone to obtain adequate separation of low molecular weight metal-binding protein fractions.

5408 THYROID CALORIGENESIS IN ISOLATED, PERFUSED RAT LIVER: MINOR ROLE OF ACTIVE

SODIUM-POTASSIUM TRANSPORT. (Eng.) Folke, M.; Sestoft, L. (Inst. Medical Physiology, Dept. A, Univ. Copenhagen, Panum Inst., DK-2200 Copenhagen, Denmark). *J. Physiol. (Lond.)* 269(2):407-419; 1977.

The hypothesis that the calorigenic response to thyroid hormone is mainly due to increased energy utilization by the membrane-bound enzyme system ($Na^+ + K^+$)-activated adenosine triphosphatase (Na-K-ATPase) was examined. The effects of ouabain on hepatic oxygen uptake, cell membrane potential, and Na-K transport were examined at 37 C during nonrecirculating perfusion of isolated livers from fasted normal Wistar rats and rats treated with triiodothyronine (T_3, 50 μg/100 g). The perfusate was Krebs-Ringer bicarbonate buffer containing albumin and bovine RBC. Treatment with T_3 increased the rate of hepatic oxygen uptake by 30% (i.e., by 0.83 μmol/min/g liver). After shifting to perfusate containing 2.5 mM ouabain, a 4-5 mV depolarization and maximal rates of net hepatic K release and Na uptake occurred within 2 min in both thyroid states. These changes were not accompanied by any significant change in the rates of hepatic oxygen uptake. T_3-treatment increased the maximal, postouabain net flux of K by 29% (i.e., by 0.52 μEq/min/g liver). The T_3-induced increase in the net flux of Na (19%) did not achieve statistical significance. In either thyroid state, the observed passive fluxes of Na and K were calculated to be balanced by active fluxes at the expense of 5-6% of the observed rate of hepatic oxygen uptake. The results indicate that hyperthyroidism may enhance the rate of hepatic Na-K transport, but the energy expenditure due to this process appears to be too small to make any important contribution to thyroid calorigenesis in perfused rat liver.

5409 METABOLISM OF THYROID HORMONES BY CULTURED MONKEY HEPATOCARCINOMA CELLS: NONPHENOLIC RING DEIODINATION AND SULFATION. (Eng.) Sorimachi, K.; Robbins, J. (Clinical Endocrinology Branch, Natl. Inst. Arthritis, Metabolism and Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *J. Biol. Chem.* 252(13):4458-4463; 1977.

The metabolism of 3,5,3'-L-triiodothyronine (T_3) and L-thyroxine (T_4) was investigated in cultured hepatocytes (NCLP-6E) derived from a rhesus monkey hepatocarcinoma. Hormones labeled with ^{125}I in the phenolic ring were added to the medium of cell monolayers. After the addition of T_3, the concentration of ^{125}I in the medium fell to approximately 50% of the starting level within 30 min. At 37 C, but not at 4 C, this was followed by a rise to approximately 90% within 5 hr. Chromatographic analysis showed almost complete disappearance of T_3, and the sequential appearance of 3,3'-L-diiodothyronine (T_2), 3'-L-monoiodothyronine (T_1) and a component, which was shown by sulfatase treatment to be the phenolic sulfate conjugates of T_2 and T_1. The T_2 sulfoconjugate accounted for about 85% of the ^{125}I in the medium after 7 hr. ^{125}I-iodide accounted for less than 6% of the total radioactivity. At 4 C, no metabolites of T_3 were observed. T_4 was also metabolized by the cells at 37 C, but not at 4 C, although the rate was much slower. The major metabolite was 3,3',5'-L-triiodothyronine (rT_3). After 18 hr, approximately 40% of the ^{125}I in the medium was unaltered T_4, and about 20% and 15% were rT_3 and (T_2) sulfate, resp. ^{125}I-iodide accounted for approximately 20% of the total radioactivity. Labeled T_3 was not detected in the medium and accounted for no more than 1.5% of the intracellular radioactivity. After incubation of cells with ^{125}I-labeled rT_3 for 24 hr, 28% of the medium ^{125}I was T_2 sulfate, indicating that the major pathway for T_2 and I^- production from T_4 was via rT_3 deiodination. The metabolism of T_3 and T_4 was saturable, and was partially inhibited by either T_3 or T_4 at 10^{-8} M, and completely inhibited at 10^{-6} M. These results show that the NCLP-6E hepatocarcinoma cells were very active in carrying out nonphenolic ring deiodination of the thyroid hormones, as well as sulfoconjugation of the partially deiodinated products.

5410 CONCENTRATION AND DILUTION OF THE URINE IN PARTIALLY HEPATECTOMIZED, CONSCIOUS RATS. (Eng.) Perlmutt, J. H.; Kao, C. C.; Hill, P. K. (Dept. Physiology 206H, Univ. North Carolina, Chapel Hill, NC 27514). *Pfluegers Arch.* 369(3):233-238; 1977.

To determine whether renal impairment in patients with liver disease could be due to the deficiency of a factor normally produced by a healthy liver, the influence of partial hepatectomy on urinary concentrating ability and renal tissue sodium was determined in conscious Sprague-Dawley rats deprived of water for 24 hr. In comparison with a sham operation, partial hepatectomy resulted in: (a) a 50% reduction in free-water reabsorption, urinary osmolality, and osmolal urine-to-plasma ratio; (b) depression of free-water reabsorption at similar levels of osmolal clearance above 200 μl/min/ml of glomerular filtration rate during the infusion of hypertonic NaCl and vasopressin; and (c) a 30% reduction in sodium content of the renal papilla and outer medulla. The renal response to an i.v. water load (2.5% glucose infuse to 2.5% of body weight at 0.4 ml/min) was determined in sham-operated and partially hepatectomized conscious rats. By 60 min after the water load, both groups had excreted practically all of the load. However, during and for 30 min after the infusion in the partially hepatectomized group, the percentage of the water load excreted, urine flow, and free-water clearance was significantly reduced while urinary osmolality and osmolal urine-to-plasma ratio were significantly elevated. These experiments demonstrate that, shortly after partial hepatectomy, the renal concentrating ability is defective and the excretion of a water load is not grossly impaired.

5411 LONG-TERM STUDIES ON CHEMICALLY INDUCED LIVER ENLARGEMENT IN THE RAT. III. STRUCTURE AND BEHAVIOUR OF THE HEPATIC NODULAR LESIONS INDUCED BY PONCEAU MX. (Eng.) Grasso, P. Gray, T. J. B. (British Industrial Biological Res. Assoc., Woodmansterne Rd., Carshalton, Surrey, England). *Toxicology* 7(3):327-347; 1977.

Histological and biochemical changes in the livers of rats fed the disodium salt of 1-(2,4- or mixed xylylazo)-2-naphthol-3,6-disulphonic acid (Ponceau MX) were studied over a 2-yr period. Enlarged but histologically normal livers occurred in female Wistar rats fed 2.5% Ponceau MX for 5-30 weeks. Pathological changes consisted first of cell enlargement, then of abnormal glycogen deposits, and later of irregular areas of fatty change and nodular hyperplasia. After feeding Ponceau MX for 12 months, laparotomy was carried out. Approximately half the animals had no nodules at laparotomy or at autopsy after 9 months on a normal diet. The remaining animals had nodules ranging from 2 to 10 mm diameter at laparotomy, and all of these nodules had grown to 3-30 mm at the time of autopsy. Histologically, the smaller lesions consisted of single nodules made of regular cords of cells, and the larger lesions were comprised of a conglomeration of nodules, some of which were solid and others exhibited advanced fatty change. The solid nodules were made up of normal or enlarged cells that were either disposed in regular cords or formed papillary and adenoid structures. Such structures were associated with pulmonary metastases. Fibrous bands were occasionally present between nodules. ^{3}H-thymidine uptake was most pronounced in the solid nodules, both when the animals were maintained on Ponceau MX for 21 months and when treated for only the first 12 months. These investigations indicate that histological changes precede the appearance of hepatic nodules in Ponceau MX-treated rats, which suggests that they are initially of a reactive nature. Once established, the nodules continue to grow and may either develop fatty degeneration or become malignant.

5412 INFLUENCE OF DIETARY FATTY ACIDS ON LIVER AND ADIPOSE TISSUE LIPOGENESIS AND ON LIVER METABOLITES IN MEAL-FED RATS. (Eng.)

Clarke, S. D.; Romsos, D. R.; Leveille, G. A. (Sch. Hygiene and Public Health, Johns Hopkins Univ., 615 N. Wolfe St., Baltimore, MD 21205). *J. Nutr.* 107(7):1277-1287; 1977.

As an approach to explaining the efficient inhibitory mechanism of polyunsaturated fatty acids on rat liver fatty acid synthesis, the concentration and composition of plasma unesterified fatty acids, the level of hepatic long chain acyl coenzyme A (CoA) esters, and liver cytosoloic redox state were quantitated in rats fed fat-free or fat-free plus 3% linoleate or linolenate diets. Sprague-Dawley rats were trained to eat a fat-free high carbohydrate diet from 0800 to 1100 hr each day. After adaptation to meal-eating, the fat-free diet was supplemented with 8% methyl stearate ($C_{18:0}$) or 3% methyl linoleate ($C_{18:2}$) for 7 days. In the fat-free group, hepatic utilization of acetate unit-equivalents (C_2 U) for fatty acid synthesis per mg soluble protein by the $C_{18:0}$ group was not significantly altered, whereas $C_{18:2}$ supplementation significantly depressed hepatic fatty acid synthesis (9.1 ± 0.7 nmol C_2 U/min/mg protein in fat-free versus 6.1 ± 0.7 nmol C_2 U/min/mg in 3% $C_{18:2}$). Supplemental $C_{18:2}$ also caused a significant decline in liver fatty acid synthetase and acetyl CoA carboxylase, while fat-free and $C_{18:0}$ groups displayed similar enzyme activities. Within a treatment, C_2 unit utilization for *in vivo* fatty acid synthesis was identical to that of acetyl CoA carboxylase and fatty acid synthetase activities *in vitro*. Therefore, shortly after a meal, the hepatic activities of these two enzymes appear to be functioning at near capacity. $C_{18:2}$ supplementation to the fat-free diet for 7 days caused a 25% decline in glucokinase and pyruvate kinase activities, but only pyruvate kinase was significantly depressed. In contrast, citrate cleavage enzyme and fatty acid synthetase were both significantly reduced in activity by 50%. Plasma unesterified fatty acid levels in rats fed $C_{18:2}$ for 5 days were not significantly elevated prior to a meal, although dietary $C_{18:2}$ did cause a fourfold rise in plasma free linoleate. Quantitation of long chain acyl CoA esters in freeze-clamped liver tissue of rats fed fat-free or fat-free plus 3% $C_{18:2}$ or $C_{18:3}$ diets revealed no concentration differences between treatments either before or after a meal. Similarly, lactate and pyruvate concentrations as well as the lactate:pyruvate ratios were not significantly changed by dietary $C_{18:2}$ or $C_{18:3}$. The inhibitory effects of $C_{18:2}$ or $C_{18:3}$ do not appear to be mediated through changes in total plasma free fatty acid levels, in total hepatic long chain acyl CoA concentration, or in hepatic cytosolic redox state.

5413 INTESTINAL REGULATION OF HEPATIC CHOLESTEROL SYNTHESIS: AN HYPOTHESIS. (Eng.)

Krumdieck, C. L.; Ho, K. J. (Univ. Alabama in Birmingham Medical Center, University Station, Birmingham, AL 35294). *Am. J. Clin. Nutr.* 30(2):255-261; 1977.

Evidence supporting the existence of an intestinal factor capable of stimulating hepatic cholesterogenesis is presented. When no food is present in the intestine, as during periods of total parenteral nutrition, both normal individuals and patients with familial hypercholesterolemia show a pronounced lowering of their serum cholesterol. For example, in a study with three patients with severe familial hypercholesteremia, the serum cholesterol level fell 23% (range, 19-44%) to a new lower baseline within 2 weeks of parenteral (i.v.) feeding. The loss of cholesterol during this period was estimated at about 5 g or 0.36 g/day. Such a reduction of body cholesterol is most likely attributable to a decrease of endogenous synthesis, since the fecal excretion of both neutral sterols and bile acids is diminished during i.v. feeding. Furthermore, if a portacaval shunt was performed after a postoperative regimen of i.v. alimentation, the lowered serum cholesterol level was sustained with a tendency for further decline. This observation suggests that a hypothetic intestinal factor capable of stimulating hepatic cholesterogenesis reaches the liver via the portal circulation and that, when carried first to the peripheral tissues through an artificial shunt, is either destroyed or diluted to the point where it loses its stimulatory activity upon returning to the liver. The function of this intestinal factor is to increase the synthesis of cholesterol whenever there is a need for increased amounts of intraluminal bile acids. The generation of the intestinal factor requires the presence of food in the intestine, and a diet rich in fat (but no cholesterol) should provide the best stimulus for the formation of the factor.

5414 CORRELATION BETWEEN SERUM LECITHIN-CHOLESTEROL-ACETYLTRANSFERASE ACTIVITY AND ERYTHROCYTE LIPID CONTENT DURING EXPERIMENTAL LIVER DAMAGE.

(Eng.) von Lehmann, B.; Grajewski, O.; Oberdisse, E. (Pharmakologisches Institut der Freien Universitat Berlin, Thielallee 69/73, D-1000 Berlin 33, W. Germany). *Naunyn-Schmiedebergs Arch. Pharmacol.* 298(3):211-216; 1977.

The relationship between lecithin-cholesterol-acyltransferase (LCAT) deficiency and RBC lipid content was studied in female Wistar rats with praseodymium-induced liver damage. The i.v. injection of 10 mg/kg praseodymium nitrate caused severe liver damage manifested by liver cell necroses, hepatic fat infiltration, and disturbances of serum lipid metabolism. Analysis of serum lipoprotein lipid content showed a contrasting behavior of the low and the high density lipoproteins. Unesterified cholesterol and phosphatidylcholine contents of the low density lipoproteins were slightly decreased 24 hr after praseodymium, followed by an eightfold increase after 96 hr. A pronounced diminution of unesterified cholesterol and phosphatidylcholine contents occurred in the high density lipoproteins within 24 hr, but returned to control values after 96 hr. In the RBCs, only phosphatidylcholine concentration was increased by about 30% at 72 hr. All other phospholipids showed a decrease followed by a normalization after 7 days. Unesterified cholesterol content of the RBC was not significantly altered. The serum lecithin-cholesterol-acyltransferase activity was inhibited by 90% 48-96 hr after administration of praseodymium. This inhibition was well correlated with the time course of RBC phosphatidylcholine content. Incubation of RBC with serum deficient in lecithin-cholesterol-acyltransferase activity enhanced the RBC phosphatidylcholine content. This alteration was independent of serum lipid concentrations. The incubation of RBCs from praseodymium-treated rats with serum containing normal lecithin-cholesterol-acyltransferase activity normalized the phosphatidylcholine content. The results indicate that serum lecithin-cholesterol-acyltransferase uses RBC phosphatidylcholine as a substrate, thus regulating the phospholipid pattern of the RBCs.

5415 7-KETOCHOLESTEROL: ITS EFFECTS ON HEPATIC CHOLESTEROGENESIS AND ITS HEPATIC METABOLISM IN VIVO AND IN VITRO.

(Eng.) Erickson, S. K.; Cooper, A. D.; Matsui, S. M.; Gould, R. G. (Stanford Univ. Sch. Medicine, Stanford, CA 94305). *J. Biol. Chem.* 252(15):5187-5193; 1977.

Because of the suggestion that 7-ketocholesterol may be used clinically in the treatment of familial hypercholesterolemias, the effects of this sterol on cholesterol biosynthesis and metabolism were investigated in intact rats and in the isolated, perfused rat liver. In the whole animal, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase was inhibited by 60 to 70% after feeding 0.1% or 0.5% 7-ketocholesterol in the diet for 18 hr. However, after 66 hr of continuous feeding, inhibition was no longer significant, suggesting rapid development of tolerance to the sterol. In animals that showed significant inhibition of reductase activity, the levels of liver total cholesterol and microsomal cholesteryl esters had increased. In animals that had developed a tolerance for the sterol, these levels were normal, but microsomal cytochrome P-450 had increased, suggesting induction of mono-oxygenase systems for metabolism of the sterol. 7-Ketocholesterol had toxic effects when fed at levels of 0.5% in the diet, as indicated by decreases in live and body weights after 66 hr. The addition of 7-ketocholesterol (6 mg/100 ml) to the perfusate of the isolated livers also reduced the reductase activities, in comparison to controls ($p < 0.001$). In both the intact rat and the perfused liver, 7-keto[^{3}H]cholesterol was rapidly metabolized to more polar derivatives and to cholesterol itself, primarily in the microsomal fraction. In the perfused liver, the sterol and its metabolites were rapidly excreted in bile. The proportion of radioactivity in more polar metabolites increased with time, thus providing an explanation for the rapid development of tolerance. These results suggest 7-ketocholesterol is not promising as a hypocholesterolemic agent, although it is a useful probe in the investigation of cholesterol metabolism.

5416 ABSOLUTE DEPENDENCE OF CCL_4 INDUCED LOSS OF GLUCOSE-6-PHOSPHATASE AND CYTOCHROME P-450 ON LIPID PEROXIDATION.

(Eng.) Recknagel, R O.; Hruszkewycz, A. M.; Glende, E. A., Jr. (Sch. Medicine, Case Western Reserve Univ., 2119 Abingto Rd., Cleveland, OH 44106). *Panminerva Med.* 18(9/1 375-380; 1976.

The mechanism for CCl_4-induced glucose-6-phosphata (G-6-Pase) and cytochrome P-450 loss was investigated in isolated rat liver microsomes. Lipid per oxidation was prevented by carrying out the initia microsomal incubation under anaerobic conditions, and with EDTA. If lipid peroxidation was prevente during the anaerobic conversion of CCl_4 to $CHCL_3$, no detectable diminution of microsomal cytochrome P-450 or G-6-Pase occurred. When an exactly equivalent system was made aerobic, and with no added EDTA, cytochrome P-450 and G-6-Pase activities decreased markedly; lipid peroxidation occurred vigorously at this time. Cleavage of the CCl_3-Cl bon catalyzed by rat liver microsomes, was totally unable to produce any significant decrease in either cytochrome P-450 content of G-6-Pase activity, provided lipid peroxidation was present. The suggestion that covalent binding of cleavage products of CCl_4 metabolism may be the key event intervening between initial CCl_3-Cl bond cleavage and loss of cytochrome P-450 and G-6-Pase was investigated by studying the fate of the two enzymes during covale binding of ^{14}C from metabolism of $^{14}CCl_4$. For 120 min of incubation, during which there was extensive covalent binding of ^{14}C from added $^{14}CCl_4$, microsomal cytochrome P-450 and G-6-Pase activities were stable. The results indicate that CCl_3-Cl bond cleavage and covalent binding of carbon from CCl_4 do not, in and of themselves, constitute a mechanism for CCl_4-induced G-6-Pase and cytochrome P-450 loss; CCl_4-induced loss appears to require lipid peroxidation as an obligatory intermediate process.

5417 CHANGES IN LIVER COMPOSITION IN PHENOBARBITAL-INDUCED HEPATOMEGALY. (Eng.)

Shenoy, S. T.; Peraino, C. (Argonne Natl. Lab., Argonne, IL 60439). *Exp. Mol. Pathol.* 27(1):134-141; 1977.

To characterize the molecular changes associated with growth stimulation, the levels of poly(A)-RNA (heterogeneous nuclear RNA + cytoplasmic messenger RNA [mRNA]), total RNA, DNA, and protein were compared in untreated rats and those with phenobarbital (80 mg/kg/day, 3 days, i.p.)-induced hepatomegaly. Total poly(A)-RNA, isolated by phenol extraction and purified by affinity chromatography on oligo-(dT)-cellulose, was assayed for its template (messenger RNA) activity in a cell-free protein synthetic system derived from wheat germ. The cell-free system was sufficiently sensitive to detect differences of less than a microgram of mRNA when optimal concentrations of Mg^{2+} and K^+ were used. Using this system, no significant differences in the hepatic content of poly(A)-RNA were observed between the control and treated groups. The DNA level was also unchanged, but the liver weight was increased by 26% in the treated group. Total RNA and protein levels also increased significantly (25% and 38%, resp., per 100 g body weight, and 21% and 30%, resp., per unit of DNA) in the treated group. Protein levels, when expressed in terms of poly(A)-RNA, showed a significant (22%) increase in the treated group. These results suggest that phenobarbital-induced hepatomegaly: (a) is characterized by hypertrophy (cell enlargement), (b) is not mediated by a generalized increase in the level of poly(A)-RNA, but involves a generalized increase in the synthesis and/or stabilization of RNA other than functional message, and (c) involves an increased translation of mRNA *in vivo*.

5418 HEXOBARBITAL-OXIDATION IN VIVO AND IN VITRO IN RATS AFTER PHENOBARBITAL-PRETREATMENT OR AFTER PORTACAVAL ANASTOMOSIS. (Ger.)

Richter, E.; Gallenkamp, H.; Brachtel, D.; Grun, M. (Med. Univ.-Klinik Wurzburg, Josef-Schneider Strasse 2, 8700 Wurzburg, W. Germany). *Z. Gastroenterol.* 15(6):389-392; 1977.

Hexobarbital (HX) oxidation was measured *in vivo* and *in vitro* in male rats after phenobarbital (PB, 50-80 mg/kg for 5 days) pretreatment or after portacaval anastomosis. HX was given at 80 mg/kg i.v.; plasma levels were determined by gas chromatography, whereas HX clearance was calculated from the plasma concentration curve versus time. Liver microsomes were obtained after homogenization, and cytochrome P450 was measured. Microsomal HX metabolism *in vitro* was measured by substrate determination after 30 min incubation at a substrate concentration of 3×10^{-4} M and a NADPH concentration of 2×10^{-3} M in Tris-HCl buffer at pH 7.4. Following PB treatment, rats had an enlarged liver, markedly raised cytochrome P450 content, elevated NADPH-cytochrome-C-reductase activity, and an increased HX oxidation rate and clearance. After portacaval shunt, the animals had a small liver, reduced cytochrome P450 level, and reduced HX oxidation and clearance. The results suggest that HX clearance *in vivo* may be a good indicator for hepatic cytochrome P450 content and hepatic HX oxidation rate, as well as for determination of drug metabolism in the liver.

5419 BILE SECRETION IN SELECTIVE BILIARY OBSTRUCTION: ADAPTATION OF TAUROCHOLATE TRANSPORT MAXIMUM TO INCREASED SECRETORY LOAD IN THE RAT.

(Eng.) Adler, R. D.; Wannagat, F. J.; Ockner, R. K. (San Francisco Medical Center, San Francisco, CA 94143). *Gastroenterology* 73(1):129-136; 1977.

Bile secretory function was studied in rats with selective biliary obstruction (SBO), in which ligation of the bile ducts draining the median and left hepatic lobes obstructs about two-thirds of liver mass. In addition, the maximum secretory capacity (Tm) for taurocholate was measured in selectively obstructed rats and in rats with intact bile ducts and expanded bile acid pools. Forty-eight hours after SBO, serum total bile acid was increased 13-fold, and total bile acid concentration in the obstructed lobes of the liver was 3 times higher than controls, but biliary secretion of water, bile acids, cholesterol, and phospholipids by the nonobstructed lobes was similar to controls when expressed per 100-g rat. In the selectively obstructed rats, but not in controls, *Tm* increased 50% between 4 and 48 hr after surgery, and, when expressed per gram of nonobstructed liver, was 81% higher than controls at 48 hr (0.69 ± 0.06 versus 0.38 ± 0.02 μmol/min/g). The rise in *Tm* between 4 and 48 hr suggests that the augmentation of *Tm* in SBO rats at 48 hr represents an adaptive response rather than recruitment of immediately available secretory reserve. The mechanism for these alterations in *Tm* was investigated in rats with intact bile ducts subjected to intraduodenal taurocholate infusion for 48 hr. In these rats doubling of bile acid pool size and secretion rate was associated with a 50% increase in taurocholate *Tm*. These findings suggest that the maximum secretory capacity for bile acids is not fixed, but rather can adapt to a sustained increase in secretory load. This observation may provide the basis for further functional and structural clarification of the process of bile secretion.

5420 HEPATIC STORAGE AND BILIARY TRANSPORT MAXIMUM OF TAUROCHOLATE AND TAUROCHENODEOXYCHOLATE IN THE DOG.

(Eng.) Poupon, R.; Poupon, R.; Dumont, M.; Erlinger, S. (Hopital Beaujon, F 92110 Clichy, France). *Eur. J. Clin. Invest.* 6(6):431-437; 1976.

A study was undertaken to examine the validity of the multiple infusion technique, previously used for the study of hepatic BSP transport, and to obtain estimates of the relative storage capacities and secretory transport maxima for taurocholate (TC) and taurochenodeoxycholate (TCDC) in dogs. The endogenous bile acid pool was depleted and the bile was collected continuously. TC and TCDC were infused i.v. at three different rates, and serum bile acid concentrations were measured at intervals of 10 min. In the last 30 min of each infusion period, serum bile acid concentration changed linearly with respect to time, with linear correlation coefficients ranging from 0.95 to 0.99. The mean hepatic relative storage capacity for TC and TCDC was 0.16 ± 0.07 and 0.09 ± 0.03 (μM/kg body weight), resp. The mean secretory transport maximum (in μM/min/kg body weight) of TC was 4.84 ± 1.24 when calculated and 4.50 ± 0.81 when measured, and of TCDC was 3.56 ± 0.06 by calculation and 3.29 ± 0.09 by measurement. The value of the secretory transport maximum was slightly higher and of the relative storage capacity was lower with the multiple infusion method as compared to direct measurement of biliary secretion. The biliary secretion of bile acids achieved a maximal rate 20 min after the start of infusion and was independent of the serum bile acid concentration. The procedure is not applicable to man because of potential toxicity due to the high concentration (220-1,000 μM) of serum bile acid used.

5421 TAUROLITHOCHOLATE-INDUCED CHOLESTASIS: TAUROCHOLATE, BUT NOT DEHYDROCHOLATE, REVERSES CHOLESTASIS AND BILE CANALICULAR MEMBRANE INJURY. (Eng.) Layden, T. J.; Boyer, J. L. (Veterans Admin. West Side Hosp., Abraham Lincoln Sch. Medicine, 820 S. Damen Ave., Chicago, IL 60612). *Gastroenterology* 73(1):120-128; 1977.

The effect of simultaneous equimolar infusions of either dehydrocholate (DHC) or taurocholate on taurolithocholate (TLC)-induced changes in bile secretion and bile canalicular membrane morphology was studied in male Sprague-Dawley rats to determine whether TC prevents TLC-induced cholestasis through its choleretic action or by its micelle-forming properties. When TC (0.8 μmol/min) was simultaneously infused for 1 hr with TLC (0.6 μmol/min), bile flow increased by 45%, in contrast to combined DHC (0.8 μmol/min) and TLC infusions where bile flow was observed to decline by 20%. When TLC was infused alone, bile flow declined by 65%, and a parallel reduction in ^{14}C-erythritol clearance was also observed although ^{3}H-inulin clearance remained unchanged. This maintenance of the clearance of ^{3}H-inulin corresponded with a threefold rise in bile to plasma ^{3}H-inulin ratios from the preinfusion ratio of 0.079 ± 0.005 to 0.241 ± 0.050, 50 min after infusion of TLC. Using equations previously described to relate inert solute clearance to bile flow, the rise in bile to plasma ^{3}H-inulin ratios and the maintenance of ^{3}H-inulin clearance was best explained by an increase in diffusion permeability of the biliary tract. Simultaneous infusions of TC prevented TLC-induced changes in inulin permeability to a greater extent than simultaneous infusions of DHC. TC also reversed the injurious effect of TLC on the scanning electron microscopic appearance of the bile canalicular membrane, whereas DHC only partially prevented these changes. These results suggest that TLC induces cholestasis in part by increasing biliary membrane permeability to bile, and that TC may prevent TLC cholestasis and canalicular membrane injury primarily by its capacity to solubilize TLC in mixed micelles.

5422 FACILITATION OF HEPATIC UPTAKE OF PHENOL 3,6-DIBROMPHTHALEIN DISULFONATE BY TAUROCHOLATE. (Eng.) Marinovic, Y.; Glasinovic, J. C.; Semelle, B.; Boivieux, J. F.; Erlinger, S. (Hopital Beaujon, 92110 Clichy, France). *Am. J. Physiol.* 232(6):E560-E564; 1977.

The influence of sodium taurocholate (TC) on the hepatic uptake of phenol 3,6-dibromphthalein disulfonate (dibromosulphophthalein, DBSP) was examined in dogs. Single injections of DBSP (7.5-83.3 mg/kg) were given i.v., and the initial velocity of uptake (V) of the dye was calculated from the plasma disappearance rate measured during the first 5 min. The initial velocity of uptake of DBSP increased with the dose (D) in a nonlinear way, a finding consistent with Michaelis-Menten kinetics. The maximal initial velocity of uptake (V_{max}) was 7.5 ± 1.0 mg/min/kg, and the half-saturation constant (K_d) was 27.7 ± 7.0 mg/kg. When a TC infusion was given prior to the DBSP injection, the initial disappearance of the dye was more rapid than in the absence of the bile acid; V_{max} increased to 12.3 ± 2.0 mg/min/kg ($p<0.001$) and K_d increased to 50.3 ± 12.8 mg/kg ($p<0.001$). These results indicat that the uptake of DBSP by the liver cell is a saturable process and that TC increases both the V_{max}, suggesting a facilitation of the uptake process, and the K_d, suggesting competition for a common site. This effect of TC on DBSP uptake is similar to the previously described effect of this bile salt on BSP excretion into bile and suggests interaction of bile salts with the uptake process of dyes.

5423 INFLUENCE OF HEPATIC TAURINE CONCENTRATION ON BILE ACID CONJUGATION WITH TAURINE. (Eng.) Hardison, W. G. M.; Proffitt, J. H. (Veterans Admin. Hosp., San Diego, CA 92161). *Am. J. Physiol.* 232(1):E75-E79; 1977.

The relationship between hepatic taurine concentration and the proportion of infused sodium cholate conjugated with taurine was studied in the perfuse rat liver. The isolated perfused liver was studie to eliminate possible transfer of taurine to or from the large extrahepatic pools present *in vivo*. During cholate infusion, the proportion of taurocholate excreted in bile decreased, and the proportion of glycocholate increased in a complementary fashion. Infusion of taurine with cholate prevente these changes. Hepatic taurine concentration, calculated from measured hepatic taurine concentratio before and at the end of cholate infusion, fell. Fall in proportion of total bile acid excreted as taurocholate was most rapid at low hepatic taurine concentrations between 1.4 and 0.65 μmol/g liver. Hepatic taurine concentration is a major determinant of the proportion of bile acid conjugated with taurine.

5424 HEPATIC UPTAKE AND BILIARY EXCRETION OF A BILE SALT ANALOG: GLYCODIHYDROFUSIDATE.

(Eng.) Montet, J. C.; Gerolami, A.; Durbec, J. P.; Crotte, C.; Montet, A. M.; Hauton, J. C. (Groupe de Recherches INSERM sur le Transport des Lipides [U 130] et Unite de Pathologie Digestive [U 31], 13009 Marseille, France). *Biomedicine* 26(1):60-64; 1977.

Hepatic uptake and biliary excretion of glyco-24,25-ihydrofusidate (GDHF) were studied in male Wistar rats. Two groups of six rats were perfused in the femoral vein, with one group receiving 0.15 M sodium chloride and the other group receiving 10 μmol/min/kg sodium dehydrocholate; 30 min after the onset of perfusion, all rats received a single i.v. injection of 3 μmol GDHF (1 μCi). The fractional transfer rate (blood towards liver) of GDHF was significantly ($2p<0.05$) higher in control rats (sodium chloride treated) than in dehydrocholate-treated rats, with the values being 1.091 ± 0.030/min versus 0.585 ± 0.056/min, resp. The fractional transfer rates for liver towards blood transport were not significantly different for control versus dehydrocholate-treated rats, being 0.059 ± 0.006/min and 0.053 ± 0.003/min, resp. The fractional transfer rate of GDHF from the liver to the bile was 0.083 0.007/min for control rats, but was significantly reduced ($2p<0.05$) in dehydrocholate-treated rats 0.030 ± 0.003/min). It is suggested that the uptake and biliary excretion of GDHF involves, at least partially, the transport mechanisms employed for bile salts.

5425 FETAL BILE SALT METABOLISM: THE INTESTINAL ABSORPTION OF BILE SALT.

(Eng.) Lester, R.; Smallwood, R. A.; Little, J. M.; Brown, A. S.; Piasecki, G. J.; Jackson, B. T. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *J. Clin. Invest.* 59(6):1009-1016; 1977.

The intestinal absorption of sodium taurocholate was studied in near-term fetal and neonatal dogs. Absorption rates were measured *in vivo* in isolated loops of fetal jejunum and ileum. Absorption was also measured *in vitro* in everted sacs and rings of fetal and neonatal jejunum and ileum. The maximal rates of taurocholate absorption, after instillation of 1 μmol taurocholate into closed segments of fetal jejunum and ileum with intact blood supply, were similar (0.282 ± 0.026 and 0.347 ± 0.051 μmol/hr/10-cm segment length jejunum and ileum, resp.). The rates of absorption from open segments of jejunum and ileum perfused with 0.4 and 1.0 mM taurocholate were also similar, 0.232 ± 0.040 and 0.255 0.039 μmol/hr, resp. at 0.4 mM, and 0.470 ± 0.065 and 0.431 ± 0.013 μmol/hr, resp., at 1.0 mM. At perfusate concentrations of 4.0 mM, moreover, jejunal absorption exceeded ileal absorption (1.490 0.140 and 0.922 ± 0.200 μmol/hr, resp. ($p<0.05$). The mucosal taurocholate concentration was readily demonstrated in adult ileal, but not in adult jejunal, everted rings. In contrast, there were no significant differences in mucosal uptake of taurocholate by fetal jejunal and ileal rings. Fetal ileal mucosal concentrations were not significantly above those in the incubation medium after 1-hr exposure of the mucosa to 0.003, 0.03, and 0.3 mM taurocholate. Uptake was proportional to the incubation medium concentration over the full range of values. This was also true of tissues from 1-week-old neonates. However, by 2 weeks of age, ileal mucosal concentration of taurocholate was evident, and adult levels were attained by 5 weeks of age. It is concluded that taurocholate is absorbed by the fetal gut and that ileal absorption is no more efficient than jejunal absorption. Although active glucose transport was demonstrable in both jejunum and ileum, it was not possible to demonstrate an ileal mechanism for active transport of taurocholate in the fetus. Active ileal transport was not demonstrable in the newborn until at least 2 weeks after birth.

5426 RADIOIMMUNOASSAY OF BILE ACIDS: DEVELOPMENT, VALIDATION, AND PRELIMINARY APPLICATION OF AN ASSAY FOR CONJUGATES OF CHENODEOXYCHOLIC ACID.

(Eng.) Schalm, S. W.; van Berge-Henegouwen, G. P.; Hofmann, A. F.; Cowen, A. E.; Turcotte, J. (Univ. Hosp., Dijkzigt, Rotterdam, Netherlands). *Gastroenterology* 73(2):285-290; 1977.

A rapid, sensitive, precise radioimmunoassay for conjugates of chenodeoxycholic (chenic) acid was developed and validated. Immunogen was prepared with chenylglycine coupled to bovine serum albumin, emulsified in Freund's complete adjuvant, and injected intracutaneously in rabbits. Antibodies of moderate titer (used at 1:7,500 final dilution) were obtained. Tracer of high specific activity was prepared by reductive tritiation of Δ^{11}-chenylglycine. The binding step required 1 hr at room temperature; separation of bound tracer was achieved by addition of ammonium sulfate. The limit of sensitivity of the assay was about 20 nM, and the lower limit of the working range was 0.4 μM. The assay was validated by measuring levels in samples of fasting state serum to which known amounts of chenylglycine had been added; the assay was also validated by means of gas-liquid chromatography on sera from jaundiced patients. The median fasting state serum level in 56 patients was 0.9 μM (upper limit of normal being 2.3), which is in the same range as that reported by others using gas-liquid chromatography. A 5- to 10-fold increase in levels of chenyl conjugates was observed 1 hr after the ingestion of a liquid meal in healthy persons. These results indicate that a satisfactory radioimmunoassay for conjugates of chenic acid has been developed.

5427 RELATIONSHIP BETWEEN BILE FLOW AND Na$^+$, K$^+$-ADENOSINETRIPHOSPHATASE IN LIVER PLASMA MEMBRANES ENRICHED IN BILE CANALICULI.

(Eng.) Reichen, J.; Paumgartner, G. (Dept. Clinical Pharmacology, Univ. Berne, Berne, Switzerland). *J. Clin. Invest.* 60(2):429-434; 1977.

The relation between bile flow and Na^+, K^+-ATPase activity in liver plasma membranes enriched in bile canaliculi was studied in rats treated with ethinyl estradiol (5 mg/kg/day, s.c., 5 days), phenobarbital (80 mg/kg/day, i.p., 4 days), or 20-methyl cholanthrene (20 mg/kg/day, i.p.). Bile flow in controls (1.49 ± 0.12 μl/min/g liver) was significantly higher than that in animals treated with estradiol (0.92 ± 0.31 μl/min/g), significantly lower than that in animals treated with phenobarbital (2.50 ± 0.21 μl/min/g), and similar to that in animals treated with 20-methyl cholanthrene or the solvent propanediol (1.62 ± 0.18 and 1.64 ± 0.30 μl/min/g, resp.). The corresponding values for canalicular Na^+, K^+-ATPase activity were 80.7 ± 19.2, 50.0 ± 18.4, 231.7 ± 42.6, 82.7 ± 30.7, and 143.6 ± 55.3 μmol inorganic phosphate/hr/g liver, resp. Canalicular Na^+, K^+-ATPase activity was significantly correlated ($r=0.785$, $n=31$) with bile flow. These findings support the hypothesis that a fraction of bile flow is related to Na^+, K^+-ATPase activity and canalicular Na^+ transport.

5428 PURIFICATION AND CHARACTERIZATION OF HUMAN LIVER-SPECIFIC MEMBRANE LIPOPROTEIN (LSP).

(Eng.) McFarlane, I. G.; Wojcicka, B. M.; Zucker, G. M.; Eddleston, A. L. W. F.; Williams, R. (King's Coll. Hosp. and Medical Sch., London SE5 8RX, England). *Clin. Exp. Immunol.* 27(3):381-390; 1977.

The purification and characterization of human liver-specific membrane lipoprotein (LSP), present in 105,000 x *g* supernatants of human liver, are reported. LSP is present in homogenates of human kidneys, spleen, adrenal, thyroid, or submaxillary gland extracts. LSP cross-reacts immunologically with antigen(s) on the surface of isolated rabbit hepatocytes. Although very labile, LSP was prepared in a stable form by gel filtration on Sepharose 6B in a Tris buffer containing 1 mM disodium EDTA. LSP was also stable in a borate buffer containing EDTA, but was unstable in a number of other buffer systems. When prepared by the above method, LSP contained approximately 2% albumin as the only detectable contaminant. Gel filtration studies on the apoprotein of LSP revealed that it has an apparent molecular weight between 4 and 20 x 10^6. Sodium dodecylsulfate polyacrylamide gel electrophoresis indicated that the lipoprotein may be composed of up to 13 subunits of different molecular sizes. The purification of LSP in stable form will facilitate further investigation of its suggested role in the pathogenesis of chronic active hepatitis. In particular, it may now be possible to develop a sensitive technique for the detection of antibodies to this antigen. This may provide a valuable tool in the diagnosis of chronic active hepatitis and for the monitoring of the effects of therapy in patients with this disease, since recent evidence suggests that a humoral response to LSP may be of central importance in the continuing hepatocellular necrosis.

5429 EFFECT OF COLCHICINE, CYCLOHEXIMIDE AND CHLOROQUINE ON THE HEPATIC TRIACYLGLYCERO HYDROLASE IN THE INTACT RAT AND PERFUSED LIVER.

(Eng.) Chajek, T.; Friedman, G.; Stein, O.; Stein, Y. (Hadassah Univ. Hosp., Jerusalem, Israel). *Biochim. Biophys. Acta* 488(2):270-279; 1977.

Hepatic triacylglycerol hydrolase activity was studied in the intact rat and in isolated perfused rat liver. Using cycloheximide (0.5 mg/100 g, i.p.) to inhibit protein synthesis in intact rats, the half life ($T_{1/2}$) of total enzyme activity in the liver was 4.6 hr. Using nonrecirculating perfusion, the heparin-releasable fraction of liver triacylglycero hydrolase was shown to comprise about 30% of the total activity; maximal rates of release were obtained within 2 min of perfusion. Following pretreatment with colchicine (0.5 mg/100 g, i.p.), th fraction was reduced to only 13%, while total enzym activity remained the same as in controls. Contra to these findings, the fall in total enzyme activi 3 hr after cycloheximide was accounted for mainly by a fall in residual activity, while the heparin-releasable activity fell only between 3 and 6 hr after inhibition of protein synthesis. These findings indicate that this triacylglycerol hydrolase is synthesized in the liver and is delivered to the cell surface through a vesicular transport system and that this transport apparently continues t operate 3 hr after inhibition of protein synthesis The fact that pretreatment of intact rats with chloroquine (7.5 mg/100 g followed by 5 mg/100 g every 2 hr) increased enzyme activity 26% suggests that lysosomal enzymes may participate in the degradation of the enzyme. The enzyme may reside near a lipoprotein remnant receptor, and it may be interiorized during remnant endocytosis.

5430 EFFECT OF ACUTE MURINE HEPATITIS (MHV-A 59) ON ETHANOL OXIDATION IN VIVO. (Eng

Carter, E. A.; Wands, J. R.; Isselbacher, K. J. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 73(2):321-326; 1977.

The effect of mild, moderate, and severe hepatitis infection induced by murine hepatitis A-59 virus on ethanol metabolism was investigated *in vivo*. Female outbred Charles River mice were injected i. with 8, 12, and 16 complement fixation units of virus, which produced liver damage ranging from mild (3-4 foci of necrosis and inflammation per hepatic lobule) to severe hepatitis (destruction o 70%-90% of hepatocytes). Ethanol oxidation was measured 48 hr after infection, when maximal cell damage was present as determined by light microsco and SGOT values. Ethanol (2.4 g/kg) was injected i.p., and the rate of ethanol oxidation was measu by cumulative production of $^{14}CO_2$ from ^{14}C-ethanol sequential serum ethanol levels; and ethanol clea ance using a s.c. air bubble technique. Using these methods there was no difference in ethanol oxidation between infected and control animals ($p<0.2$). 4-Methylpyrazole (100 mg/kg) produced a 80% reduction in cumulative $^{14}CO_2$ production, prevented a progressive decline in blood ethanol leve and abolished the ethanol clearance in control mi over a 3-hr period. A marked depression of *in vivo* oxidation of ^{14}C-aminopyrine oxidation to $^{14}CO_2$ was observed in animals with severe hepatitis ($p<0.001$). Mild, moderate, and severe murine hepatitis appears to have no effect on ethanol oxidation *in vivo*, but does exert a marked inhibitory effect on microsomal enzyme function.

5431 EFFECT OF RIBAVIRIN ON VIRAL HEPATITIS IN LABORATORY ANIMALS.

(Eng.) Sidwell, R. W.; Huffman, J. H.; Campbell, N.; Allen, L. B. (ICN Pharmaceuticals, Inc., Irvine, CA 92715). *Ann. N.Y. Acad. Sci.* 284:239-246; 1977.

The effect of 1-β-D-ribofuranosyl-1,2,4-triazole-3-carboxamide (ribavirin) on male Swiss Webster mice and female Syrian golden hamsters inoculated i.p. with about 10 times the LD$_{50}$ of murine hepatitis virus (MHV, Friend-Braunsteiner strain) and equine abortion virus (EAV), resp., was investigated. The drug was administered i.p. twice daily, beginning 1 hr before virus inoculation and continuing for 4 days in the case of EAV-infected hamsters or beginning 2 hr before virus inoculation and continuing for 9 days in the case of MHV-infected mice. At a dose of 200 mg/kg/day, ribavirin caused a 2.2-day increase in the mean survival time of EAV-infected hamsters ($p<0.05$), and 20% of the treated hamsters survived infection as compared with a 0% survival for controls. Ribavirin at a dose of 100 mg/kg/day was not effective; it was lethally toxic at doses of 300 and 400 mg/kg/day. In MHV-infected mice, ribavirin at doses of 4.7-75 mg/kg/day was effective in increasing the mean survival from control values of 4.4 and 4.8 days to values as high as 7.2 and 21.0+ days in two sets of experiments ($p<0.05$ in all cases). At doses of 18.8 mg/kg/day and greater, ribavirin also significantly increased the number of survivors ($p<0.001$ at this dose). Ribavirin treatment delayed the increase in SGOT levels seen in virus-infected mice, although by day 5, a moderate increase from a preinjection value of about 50 S-F U/ml to about 225 S-F U/ml was seen. Ribavirin treatment in both infected and uninfected mice caused an initial, moderate rise in bilirubin on day 1 from a preinoculation value of about 0.75 mg% to over 1.0 mg%; this rise then declined by day 3 to less than 1.0 mg% and then rose in virus-infected, ribavirin-treated mice on day 5 to about 1.4 mg%. Marked damage was plainly visible in the livers of virus-infected control animals, but was notably less apparent in ribavirin-treated animals. The results indicate that ribavirin has a marked effect on hepatitis in MHV-infected mice and a marginal effect on hepatitis in EAV-infected hamsters.

5432 BILIARY EXCRETION OF IOPANOATE GLUCURONIDE BY THE RAT.

(Eng.) Cooke, W. J.; Cooke, L. (Univ. Massachusetts Medical Sch., 55 Lake Ave. North, Worcester, MA 01605). *Drug Metab. Dispos.* 5(4):368-376; 1977.

Biliary excretion, plasma decay, and tissue distribution of ^{125}I after a single i.v. dose (13 μmol/kg) of ^{125}I-iopanoate and ^{125}I-iopanoate glucuronide were compared in control and phenobarbital-pretreated rats under ether anesthesia. In control animals, the plasma decay of iopanoate glucuronide following iopanoate glucuronide administration was significantly greater than that after iopanoate administration ($T_{½}=26.3 \pm 2.4$ min versus 58.2 ± 3.2 min, $p<0.05$). Biliary clearance following iopanoate glucuronide was approximately 20 times greater than that after iopanoate; within 60 min, 82% of the dose of iopanoate glucuronide, compared to 23% of the dose of iopanoate, was recovered in bile. Phenobarbital (40 mg/kg/day, x 3) pretreatment significantly increased the biliary excretion following iopanoate administration (36.3 ± 3.1% of dose excreted/60 min versus 26.1 ± 1.0%, $p<0.05$), but had no effect on that following iopanoate glucuronide. The urinary excretion after both agents was less than 3% of the administered dose within the 60-min experimental period. The data suggest that intracellular metabolism and/or binding may account for the marked difference in the biliary excretion of iopanoate glucuronide following iopanoate as compared to that after administration of iopanoate glucuronide.

5433 EFFECT OF BILE DUCT OBSTRUCTION ON PANCREATIC ENZYME SECRETION AND INTESTINAL PROTEOLYTIC ENZYME ACTIVITY IN THE RAT.

(Eng.) Green, G.; Nasset, E. S. (Children's Hosp. Medical Center, 51st and Grove St., Oakland, CA 94609). *Am. J. Dig. Dis.* 22(5):437-444; 1977.

The role of bile in the regulation of intestinal proteolytic activity in male HLA-W Wistar rat descendants was investigated by studying the effects of bile diversion and bile duct obstruction on pancreatic protease secretion and on recovery of protease from the small intestine. Diversion of bile and pancreatic juice from the intestine caused a large increase in pancreatic enzyme secretion, which reached a maximum value of about 55 x 10^3 benzoyl-1-tyrosine ethyl ester (BTEE) U/hr for chymotrypsin at 3 hr after diversion; replacement of bile partially suppressed this response. Bile duct obstruction resulted in a threefold increase in pancreatic juice chymotrypsin at 3-4 days post-obstruction, but caused a marked decrease in intestinal trypsin (378 ± 45 to 156 ± 19 x 10^3 tosyl-1-arginine methyl ester-TAME-U/rat, $p<0.01$), chymotrypsin (624 ± 89 to 101 ± 20 x 10^3 BTEE U/rat, $p<0.005$), and total proteolytic activities (742 ± 78 to 442 ± 63 U/rat, $p<0.025$). The percentage of recovery from the intestines of bile duct obstructed rats was lower for trypsin (34.2 ± 4.7, $p<0.05$), chymotrypsin (8.3 ± 2.7, $p<0.005$), and pancreatic juice protein (26.2 ± 3.5, $p<0.025$) than for control values (41.9 ± 3.0, 39.2 ± 3.8, and 39.0 ± 1.3, resp.). Bile duct obstruction did not influence the efficiency of washing in recovering intestinal trypsin activity, but decreased the efficiency of washing in recovering chymotrypsin activity from a control value of 78% to 61%. The results suggest that interruption of bile flow results in an accelerated rate of degradation of pancreatic proteolytic enzymes and that the increase in pancreatic enzyme secretion is an adaptation to decreased intestinal proteolytic activity.

5434 HEPATOCELLULAR TRANSPLANTATION IN ACUTE LIVER FAILURE. (Eng.) Sutherland, D. E. R.; Numata, M.; Matas, A. J.; Simmons, R. L.; Najarian, J. S. (Mayo Memorial Bldg., Univ. Minnesota Hosp., Minneapolis, MN 55455). *Surgery* 82(1):124-132; 1977.

The ability of dispersed hepatocytes to provide metabolic support when transplanted to rats with dimethylnitrosamine (DMNA)-induced liver damage was studied. DMNA (20 mg/kg) was administered to 92 Lewis rats. Animals were divided into four groups receiving the following treatments 24 hr after DMNA administration: group I, i.p. transplantation of hepatocytes prepared from 2.0 g of normal isologous rat liver; group II, infusion into the portal vein of hepatocytes prepared from 1.5 g of liver; group III, infusion of saline into the portal vein; and group IV, no further treatment. The percentages surviving in each group 3 weeks after DMNA administration were 63%, 71%, 17%, and 6%, resp. Mean SGOT levels 3 days after DMNA administration were similar in the four groups, indicating that the degree of liver damage was equivalent. A significantly higher proportion of hepatocyte-treated rats survived. Rats in group III had the highest initial mortality and a long-term survival of only 17%. The long-term survival (>60 days) rates in groups I, II, and IV were 63%, 71%, and 6%, resp. Liver histology after DMNA administration showed hemorrhagic central lobular necrosis. A return to near-normal architecture occurred by 3 weeks in surviving animals. In group II, hepatocytes were seen in portal venules, sinusoids, and central veins. Dispersed hepatocytes, transplanted either i.p. or via the portal vein, can provide sufficient metabolic support to allow for recovery from drug-induced hepatic necrosis.

5439 ELECTRON MICROSCOPIC STUDIES OF THE ASSEMBLY, INTRACELLULAR TRANSPORT, AND SECRETION OF CHYLOMICRONS BY RAT INTESTINE. (Eng.) Sabesin, S. M.; Frase, S. (Dept. Tennessee Center for the Health Sciences, Memphis, TN 38163). *J. Lipid Res.* 18(4):496-511; 1977.

The assembly, intracellular transport, and secretion of chylomicrons were investigated ultrastructurally in the proximal jejunal cells of male Sprague-Dawley rats fed 1.5 ml of corn oil. Following fat feeding, the smooth endoplasmic reticulum of the absorptive cells became laden with triglyceride droplets that were transported through channels of the endoplasmic reticulum to the Golgi apparatus. The Golgi zones became extremely prominent due to the accumulation of osmiophilic droplets, similar in size and configuration to chylomicrons, within proliferated Golgi vesicles. Golgi-derived secretory vesicles, containing nascent chylomicrons, migrated towards the lateral cell membrane. The secretory vesicle membranes fused with the lateral plasmalemma, and nascent chylomicrons were then seen to be discharged into the intercellular spaces. Alteratio of specific domains of the secretory vesicles wer prominent, appearing as coated pits. Coated pits were apparent in the lateral plasmalemma in areas of active chylomicron exocytosis, suggesting thei derivation from secretory vesicle-membrane fusion Chylomicrons, within the intercellular spaces, passed through the basement membrane that lines t basal surfaces of the epithelial cells, traversed the cellular elements of the lamina propria, and finally gained access to the lymphatics entering these channels through gaps between adjacent endothelial cells. These observations indicate that nascent chylomicrons accumulate within Golgi vesicles as a prerequisite to secretion and that secr tion occurs by exocytosis, resulting in the relea of nascent chylomicrons from secretory vesicles.

5440 MORPHOLOGY AND ENZYME ACTIVITY IN RAT SMALL INTESTINAL EPITHELIUM 6 AND 12 HRS. AFTER AN ALKYLATING AGENT (CYCLOPHOSPHAMIDE). (Eng.)

Ecknauer, R. (Dept. Clinical Chemistry, Univ. Ulm, Steinhovelstr. 9, D-7900 Ulm, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(5):365-371; 1976.

Morphologic and enzymatic changes in the small intestinal epithelium of specified pathogen-free (SPF) and germfree (GF) Wistar rats were investigated 6 and 12 hr after the administration of a single i.p. dose of cyclophosphamide (100 mg/kg). In GF rats, there were no significant changes in the activity of the brush border enzymes maltase, sucrase, lactase, alkaline phosphatase, and γ-glutamyltransferase. In SPF rats, the only significant difference ($p<0.05$) in brush border enzyme activities was between the maltase activities; this difference was only significant when expressed per cm of gut length. There were no significant changes in acid phosphatase activity after drug treatment in either GF or SPF rats. Morphologically, the pattern of response to cyclophosphamide appeared to be different in SPF and GF rats. Villus height was not significantly changed in SPF rats, but GF rats showed a small reduction in villus height at 12 hr after drug treatment (589 µm versus a pretreatment height of 647 µm, $0.025<2p<0.05$). In SPF rats, the number of epithelial cells per crypt section was reduced at 12 hr (48 ± 3) in comparison with that at 6 hr (55 ± 2, $2p<0.01$). A reduction in mitotic figures per crypt 6 hr after cyclophosphamide treatment (1.4 ± 0.4) in comparison with pretreatment levels (2.1 ± 0.4) was significant only in SPF rats ($0.01<2p<0.02$). Intestinal function, as measured by galactose absorption *in vivo*, was not affected by cyclophosphamide treatment in either GF or SPF rats, whether expressed in terms of gut length, wet weight of mucosa, or gram mucosal protein.

5441 ACTIVE CHLORIDE SECRETION BY RABBIT COLON: CALCIUM-DEPENDENT STIMULATION BY IONOPHORE A23187. (Eng.)

Frizzell, R. A. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *J. Membrane Biol.* 35(2):175-187; 1977.

The possible involvement of calcium as an intracellular messenger was investigated using the Ca ionophore A23187. Addition of the ionophore to the solution bathing the mucosal surface of descending rabbit colon resulted in a reversal of active Cl absorption to active Cl secretion, a twofold increase in short-circuit current, and a 40% increase in tissue conductance, without affecting the rate of active Na absorption. These alterations in electrolyte transport are quantitatively similar to those previously observed in response to cyclic 3',5'-AMP (cAMP). When medium Ca concentration was reduced to 10^{-6} M, the secretory response to A23187 was abolished, but the response to cAMP was unaffected. The ionophore did not influence the cAMP levels of colonic mucosa. Addition of cAMP to colonic strips preloaded with ^{45}Ca elicited a reversible increase in Ca efflux from the tissue. These results suggest that an increase in intracellular Ca concentration stimulates colonic electrolyte secretion and that the secretory response to cAMP may be due, at least in part, to a release of Ca from intercellular stores.

5442 NONPARALLEL SECRETION OF ENZYMES IN HUMAN DUODENAL JUICE AND PURE PANCREATIC JUICE COLLECTED BY ENDOSCOPIC RETROGRADE CATHETERIZATION OF THE PAPILLA. (Eng.)

Dagorn, J. C.; Sahel, J.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM U 31-46 chemin de la Gaye, 13009 Marseille, France). *Gastroenterology* 73(1):42-45; 1977.

Enzyme secretion was studied in human duodenal and pancreatic juice following the administration of cholecystokinin-pancreozymin (CCK-PZ) and secretin, to determine whether different enzymes respond in parallel to hormone stimulation. Duodenal juice was collected at 15-min periods from 50 subjects free of pancreatic disease in the basal state and after the i.v. injection of CCK-PZ (3 Crick-Harper-Raper U/kg) plus secretin (1 clinical U/kg). The mean amylase to chymotrypsin ratios were decreased from a basal level of 0.081 to 0.039, 0.046, and 0.051 in the first, second, and third periods, resp. ($p<0.01$, $p<0.01$, and $p<0.05$, resp.), and the amylase to lipase ratios were decreased from a basal level of 0.925 to 0.41, 0.44, and 0.52 in the respective periods ($p<0.01$ in all cases). Pure pancreatic juice was collected from seven subjects by endoscopic retrograde catheterization of the papilla. Secretin (1 clinical U/kg/hr) was infused i.v. during 30 min, and a single i.v. injection of CCK-PZ (3 Crick-Harper-Raper U/kg) was administered at the 15th min of the secretin infusion. The chymotrypsinogen and lipase secretions did not parallel that of amylase during CCK-PZ stimulation. As in the first set of experiments, amylase secretion was proportionally less stimulated by CCK-PZ injection than were chymotrypsinogen and lipase secretions. In five of six cases, CCK-PZ stimulation induced a significant ($p<0.01$) 30-50% decrease in the amylase to chymotrypsin ratio. However, in approximately 20% of subjects, the secretion of the enzymes was parallel in both duodenal and pancreatic juice. The results on pure pancreatic juice support the finding of a nonparallel secretion of enzymes in duodenal juice.

5443 STIMULATION OF MUCOSAL GROWTH IN THE RAT ILEUM BY BILE AND PANCREATIC SECRETIONS AFTER JEJUNAL RESECTION. (Eng.)

Weser, E.; Heller, R.; Tawil, T. (Univ. Texas Health Science Center at San Antonio, San Antonio, TX 78284). *Gastroenterology* 73(3):524-529; 1977.

The role of bile and pancreatic secretions in stimulating ileal mucosal growth after jejunectomy was studied in male Sprague-Dawley rats. The animals were fed either standard rat chow or a liquid elemental diet, and were divided into four surgical groups: sham-operated, transplantation of the duodenal papilla (containing the bile and pancreatic ducts) into the ileum, 50% proximal small bowel resection (jejunectomy), and combined transplantation of the duodenal papilla into the ileum and 50% proximal small bowel resection. Four weeks after surgery, total ileal weight and mucosal weight, and DNA and protein concentration per cm of segment, were significantly increased in ileal segments adjacent to the transplanted duodenal papilla both in nonresected and jejunectomized rats, compared with their respective controls. Transplanting the duodenal papilla into the ileum significantly increased growth of the ileal mucosa after jejunectomy. The results indicate that bile and pancreatic secretions flowing into the ileal lumen stimulate mucosal growth and play a direct role in ileal adaptation to jejunal resection.

5444 THYROXINE-EVOKED DECREASE OF JEJUNAL LACTASE ACTIVITY IN ADULT RATS. (Eng.) Celano, P.; Jumawan, J.; Koldovsky, O. (Children's Hosp. of Philadelphia, Philadelphia, PA 19104). *Gastroenterology* 73(2):425-428; 1977.

Because of the known involvement of the thyroid in the expression of the normal developmental patterns of various intestinal functions, the effect of short-term hyperthyroidism on microvillar sucrase and lactase and on lysosomal acid-β-galactosidase was investigated in adult rat jejunum. The daily administration of L-thyroxine (200 μg/100 g, s.c.) decreased the total and specific lactase activity by 35%; this depression was maintained by daily injections of L-thyroxine at this dose for 3, 4, and 10 days. The injection of D-thyroxine (200 μg/100 g/day) for 4 days produced a similar decrease in lactase activity. Sucrase activity was not affected by L-thyroxine, except for a 30% increase after 10 days of treatment (200 μg/100 g/day). Sucrase activity was significantly decreased by D-thyroxine treatment. The activity of acid-β-galactosidase was unaffected by either D- or L-thyroxine. Subnormal lactase activity may be involved in the generation of diarrhea and steatorrhea in hyperthyroid patients.

5445 INHIBITION OF CHOLECYSTOKININ-PANCREOZYMIN RELEASE BY SOMATOSTATIN. (Eng.) Schlegel, W.; Harvey, R. F.; Raptis, S.; Oliver, J. M.; Pfeiffer, E. F. (Dept. Internal Medicine, Univ. Ulm, Steinhovelestrasse 9, 7900 Ulm, W. Germany). *Lancet* 2(8030):166-167; 1977.

To determine the effect of somatostatin on cholecystokinin-pancreozymin (CCK) release, serum CCK concentrations were measured in five normal volunteers after the intraduodenal administration of 40 ml of olive oil, with and without a simultaneous i.v. infusion of somatostatin (250 μg, followed by 250 μg/hr for 1 hr). After instillation of the olive oil, there was a rapid rise in serum CCK (integrated response 19,682 ± 5,632 pg/min/ml). This rise was completely abolished by somatostatin (integrated response -373 ± 330 pg/min/ml, $p<0.005$), and rebound hypersecretion was seen after the infusion had been stopped. These findings indicate that somatostatin may be involved in regulating CCK release after meals, and suggest a possible explanation for the profound steatorrhea seen in a patient with a somatostatin-producing tumor.

GENERAL

3 THE EFFECTS OF VARYING CONCENTRATIONS OF
DIETARY PROTEIN ON THE CEREBRAL GAMMA-
NO-BUTYRIC ACID OF RATS SUBMITTED TO PORTACAVAL
STOMOSIS. (Ita.) Vassanelli, P.; Norberto, L.;
chi, S.; Stella, G. D.; Settembrini, P. G. (Is-
uto di Patologia Speciale Chirurgia e Propedeu-
a Clinica, Universita di Padova, Padova, Italy).
a Chir. Ital. 31(2):295-300; 1975.

effect of protein content in the diet of animals
mitted to portacaval anastomosis was investigated.
ty male Sprague-Dawley rats were given a porta-
al shunt and divided into four equal groups. All
mals received a standard diet for 10 days. An
al number of sham-operated animals served as
trols. After 10 days, group A remained on a
ndard diet, group B received a diet of 9% protein,
up C, a diet of 34% protein, and group D a diet
0.5% protein. Animals on a standard diet had
4% increase in gamma-aminobutyric acid (GABA)
compared to controls. A diet of 34% protein resulted in a 50% increase in GABA. Animals fed 9% protein had GABA levels that were essentially the same as controls. The greatest increase in GABA content (180% over the controls) was seen in animals that received the protein-deficient diet (0.5%). These latter animals also had the most pronounced signs of encephalopathy and the highest mortality rate. It is suggested that there is a relation between cerebral GABA levels and encephalopathy.

5464 FINE STRUCTURAL CHANGES IN THE GASTRO-INTESTINAL TRACT OF THE HYPOXIC PUPPY: A STUDY OF NATURAL HISTORY. (Eng.) Harrison, M. W.; Connell, R. S.; Campbell, J. R.; Webb, M. C. (Univ. Oregon Health Sciences Center, 3181 S. W. Sam Jackson Park Rd., Portland, OR 97201). *J. Pediatr. Surg.* 12(3):403-408; 1977.

A study was undertaken to follow the structural changes in the gastrointestinal tract of the hypoxic puppy (Labrador puppies) in order to diagnose an early acute enterocolitis. Hypoxia was induced in eight puppies by increasing the flow of nitrogen until the oxygen concentration of the anesthetic gas mixture was 7%. Four control puppies were maintained in an atmosphere of 21% oxygen. Platelet and WBC aggregates, circulating lysosomal-like granules, and fibrin were present in the microcirculation of the lamina propria of the ileum and colon of puppies biopsied after 2 hr of sustained hypoxia. In the resuscitated puppy, biopsied 24 hr after the insult, these elements were not seen. However, perivascular edema and disruption of cellular elements in the lamina propria of the ileum and colon were still apparent in focal areas after 24 hr. Five days after the insult of hypoxia, the mucosa and underlying lamina propria appeared similar to those of the control puppies. It is suggested that an early focal and reversible stage of the development of acute enterocolitis could be described with the aid of electron microscopy. Death of the puppies could be predicted by the extent of microvascular and mucosal involvement.

5465 PATHOPHYSIOLOGY IN THE ACUTE AFFERENT LOOP SYNDROME. A STUDY IN RATS.

(Eng.) Bengtsson, S.; Dahlgren, S.; Hellsing, K. (Dept. Bacteriology, Univ. Uppsala, Uppsala, Sweden). *Acta Chir. Scand.* 142(6):461-466; 1976.

The acute afferent loop syndrome (occlusion of an afferent intestinal loop) following Billroth II partial gastrectomy was induced in rats to investigate the importance of osmosis during the development of the syndrome. Three groups of rats were used: controls (35 rats, rats in which the afferent loop syndrome was induced 2 months after gastroenterostomy and pyloric resection (GE, 98 rats), and rats used for complementary studies *in vitro* 4 months after GE (12 rats). The animals were killed at time intervals of 0.5, 1, 4, 8, or 12 hr after occlusion and hematocrit, serum osmolality, and the content and volume of the occluded loop were determined. In some cases, a sample of the content was incubated at 37 C, and the osmolality was determined at regular intervals. The hematocrit rose with time after the occlusion in the second group of rats (from an initial value of 31 ± 2.3 to a final value of 36 ± 2.3 12 hr after occlusion). However, the osmolality of the plasma and of the content of the occluded loop did not increase significantly. The volume of fluid in the occluded loop increased continuously with time from an average of 0.5 ml in the control group to 6.1 ml after 12 hr of occlusion. Experiments *in vitro* showed that the initial osmolality of the contents of the loop was 300 mOsm. After incubation of the samples, osmolality increased 43-146%. The bacterial content of the loop (including *Clostridium perfringens*) increased significantly. The results suggest that a marked breakdown of substances takes place in such an occluded intestinal loop, causing an increase in the osmolality. As a result, fluid is attracted to the loop to keep the osmolality constant. A combination of the fluid increase due to osmosis and contractions of the intestinal wall leads to an increased pressure in the occluded loop.

5466 BACTERIAL ASSOCIATION IN THE GASTROINTE TINAL TRACT OF BEAGLE DOGS.

(Eng.) Da C. P.; Cleven, D.; Balish, E.; Yale, C. E. (Univ. Texas Medical Branch, Galveston, TX 77550). *Appl Environ. Microbiol.* 34(2):194-206; 1977.

To determine whether the gastrointestinal tracts of adult dogs possess localized bacterial populaations and to ascertain whether different housing conditions alter the gastrointestinal flora, nine male beagle dogs, housed in either a conventional or locked environment for 2.5 yr, were killed, an the bacterial flora present in various regions of each gastrointestinal tract was assessed by cultu techniques, light microscopy, and scanning electr microscopy. All dogs possessed a complex colonic microflora; in almost every dog anaerobes predominated. The highest number of bacteria cultured was 10^{10}/g (dry weight) of tissue and contents; highest counts obtained with a Petroff-Hauser counting chamber were 10^{10}/ml (wet weight). Alth there was a consistency in the detectable genera there were also noticeable differences in the fl of dogs housed under different environmental con tions. These differences included qualitative a quantitative changes in the flora, as well as alterations in the distribution and localization of microorganisms along the gastrointestinal tra and in the crypts of Lieberkuhn. No bacterial l were detected on the surfaces of stomach or prox bowel in any of the dogs. Bacteria occurred in layers on the ceca and colons and in the crypts Lieberkuhn of dogs housed in a conventional, ope environment; however, dogs housed under "locked" environmental conditions did not possess or had layers of bacteria less frequently. Dogs remove from the locked environment and kept for 30 days in conventional housing conditions were the only ones with detectable segmented filamentous micro in their ilea. This study shows that the microb flora does not simplify when dogs are housed in locked environment. Indeed, it may increase in complexity and cause alterations in the bacteria flora that are associated closely with gastroint tinal epithelial cells and crypts of Lieberkuhn.

5467 INTESTINAL PROLIFERATION AFTER MULTIPL FRACTIONS OF GAMMA IRRADIATION.

(Eng Maisin, J.; Wambersie, A.; Lambiet-Collier, M.; Gueulette, J. (Radiobiology Dept., C.E.N., Boere tang, 200, B-2400 Mol, Belgium). *Radiat. Res.* 71(2):338-354; 1977.

To investigate recovery mechanisms in radiation- duced intestinal injury, the histological appea of duodenal mucosa in BALB/c+ mice was studied after fractionated abdominal irradiation with d doses of 200 and 350 rads. After 200 rad/day (rad/week), the average number of nuclei per tan tial section of crypts increased in two steps a reached 117, 112, 151, 140, and 145% of the con value after, 2, 3, 4, 5, and 6 weeks, resp. Th

ıverage numbers of mitoses and of [^{3}H]thymidine-
.abeled nuclei per crypt also increased to 155, 155,
.60, 207, and 221% and 190, 140, 131, 192, and 230%
ıf the controls, resp. In mice that received 350
ads/day, the number of nuclei per crypt increased
t about the same rate as in those given 200 rads,
nd the increase in the number of mitoses per crypt
nd in the mitotic index was more rapid and more
ronounced than in those given 200 rads; however,
ost animals that received 350 rads died before the
nd of the 4th week. These data suggest an in-
rease in the stem cell compartment, which is esti-
ated at 1.4 times its normal value after 4-6 weeks.
he length of the mitotic cycle (T_c) was measured
sing the usual [^{3}H]thymidine labeling technique
fter 5,000 rad/5 weeks, given in daily fractions of
00 rad. T_c was reduced from 14 to 9 hr, this re-
uction mainly concerning the G_1 phase (from 5 to
hr) and to a smaller extent the S phase (from 7
o 6 hr). Intestinal mucosa tends to compensate
or cell destruction by two mechanisms: a reduction
n the duration of the mitotic cycle and an increase
n the size of the stem cell compartment. At 200
ad/day, an important compensation is achieved, and
he animals are able to tolerate the irradiation for
bout 6 weeks. At 350 rad/day, however, increased
ell production can no longer compensate for cell
estruction, and the animals die after the third
eek.

468 DISTRIBUTION OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) IN THE RAT AS MEASURED
Y RADIOIMMUNOASSAY AND BY RADIORECEPTORASSAY.

're.) Besson, J.; Dupont, C.; Laburthe, M.;
ataille, D.; Rosselin, G. (Unite de Recherche de
labetologie, 184, rue du Faubourg Saint-Antoine,
-75571 Paris Cedex 12, France). *Ann. Endocrinol.*
'aris) 38(2):145-146; 1977.

ıe vasoactive intestinal polypeptide (VIP) content
various rat tissues was measured using a radio-
mmunoassay. The intestinal tract contained 98.5%
the VIP, with the jejunoileal section having
ıe largest quantities (59%). The brain content of
P measured 1.5% of the total. The biological
tivity of the VIP extract was confirmed with a
adioreceptorassay using liver plasma membranes as
ıe specific target tissue. The jejunoileal values
tained during this study were almost identical
.th both assay techniques. The high concentrations
VIP in these tissues suggest a role of this pep-
.de in physiological phenomena.

69 EFFECT OF LOCAL CIRCULATORY ARREST ON THE STRUCTURE OF THE ENTEROCYTES OF THE ISO-
TED INTESTINAL LOOP.

(Eng.) Varkonyi, T.; Witt-
nn, T.; Varro, V. (Univ. Medical Sch., H-6701
eged, Hungary). *Digestion* 15(4):295-302; 1977.

ıe ultrastructural effects of anoxia were studied
isolated canine loops of small intestine after
perimental mesenteric obstruction. The arterial
rculation of two adjacent intestinal segments in
ch of six dogs was arrested by clamping, and
opsies were taken 1, 3, 5, 7, and 15 min after
amping. Isotonic glucose was placed in one loop before clamping, while the other remained empty. In the empty loop, mucosal changes were first seen after 3 min of anoxia. Cytoplasmic protrusions occurred on the luminal surface of the enterocytes. The endoplasmic reticulum was also altered. By 15 min after the induction of anoxia, the development of the cytoplasmic protrusions progressed to fusion of the microvilli and breakdown of the microvillous structure. The cytoplasm was vacuolated. Filling the intestinal lumen with isotonic glucose prevented these changes. This fact suggests that intrinsic cellular energy sources can be supplemented by intraluminal glucose.

5470 THE EFFECT OF ACIDIFYING THE DUODENAL CONTENTS ON SPLANCHNIC BLOOD FLOW.

(Eng.) Benyo, I.; Jakab, F.; Sugar, I.; Szabo, G. (Semmelweis Univ. Medical Sch., Budapest, Hungary). *Acta Hepatogastroenterol.* 24(3):201-204; 1977.

The effect of duodenal acidification on splanchnic circulation was studied in mongrel dogs under pentobarbital anesthesia to examine whether increased blood flow in the liver is due to intrahepatic vascular changes or to dilation in the mesenteric vascular bed. Electromagnetic blood flow meters monitored the common hepatic arterial and portal venous flow, while 0.1 N or 0.5 N hydrochloric acid, 30% glucose solution, or physiologic saline was introduced via plastic tubes into the upper duodenum and jejunum. Acidifying the duodenal contents with 3 ml/kg of 0.1 N hydrochloric acid increased both hepatic artery and portal venous flow 24.7%, and reduced mesenteric vascular resistance as well as hepatic artery and portal venous inflow resistances by -32.5%, -25.3%, and -11.2%, resp. After intraduodenal injection of 30% glucose and physiological saline solutions, the reaction was absent. More concentrated acid led to a greater increase in blood flow. The receptors of the circulatory reflex are situated in the duodenal mucosa and can be blocked with 1% lidocaine, indicating that neurogenous factors have a definite role in the control of vascular flow by the duodenal mucosa.

5471 ALTERATIONS OF CELLULAR PROLIFERATION IN THE ILEAL EPITHELIUM OF SUCKLING AND WEANED RATS: THE EFFECTS OF ISOPROTERENOL.

(Eng.) Klein, R. M. (Univ. Kansas Medical Center, 39th St. and Rainbow Blvd., Kansas City, KS 66103). *Cell Tissue Kinet.* 10(4):353-364; 1977.

Cell proliferation in the rat ileum was compared before and after neonatal closure to macromolecules, and the effects of the sympathomimetic amine, isoproterenol (IPR), on cell cycle parameters were determined. The pre-closure ileum was represented by 8-day-old rat ileum and the post-closure ileum by 28-day-old rats. The duration of the cell cycle phases was determined by the percentage of labeled metaphases technique (PLM) with computerized analysis of the curves. The generation cycle time was longer in 8-day-old suckling rats (18.63 hr) as compared to the older weaned rats (11.85 hr), and most of this 6.78 hr difference was in the G_1-period (4.5

hr). Other proliferative indices were also lower in the suckling rats: mitotic index (1.9 ± 0.4% as compared to 6.7 ± 0.9%), labeling index (26.8 ± 2.5% versus 44.2 ± 2.6%), and migration rate measured as percent labeled villus cells (8.9 ± 3.1% versus 45.2 ± 3.4%). IPR inhibited cellular proliferation in the ileal epithelium of both age groups. The cell cycle of the ileal epithelium of 8-day-old rats was lengthened from 18.63 to 21.07 hr and of 28-day-old rats from 11.85 to 13.98 hr. IPR produced a decrease in mitotic index from 1.9 ± 0.4% to 1.6 ± 0.4% in pre-closure ileum and from 6.7 ± 0.9% to 5.1 ± 0.6% in post-closure ileum. Labeling index decreased from 26.8 ± 2.5% to 20.0 ± 2.0% in 8-day-old rats and from 44.2 ± 2.6% to 31.1 ± 3.0% in 28-day-old rats after IPR administration. There were also significant differences in growth fraction between age groups and a significant decrease in growth fraction after IPR treatment. It appears that β-adrenergic stimulation has an inhibitory effect on neonatal ileal epithelium.

5472 THE EFFECT OF TRANSPOSITION TO JEJUNUM ON EPITHELIAL CELL KINETICS IN AN ILEAL SEGMENT. (Eng.)

Rijke, R. P. C.; Hanson, W. R.; Plaisier, H. M. (Erasmus Univ. Rotterdam, P.O. Box 1738, Rotterdam, Netherlands). *Cell Tissue Kinet.* 10(4):399-406; 1977.

To clarify the regulatory mechanisms underlying epithelial cell renewal in the small intestine, epithelial cell kinetics were studied in ileal segments of rats after transposition to proximal jejunum. The number of cells per villus column in the transposed ileum increased after 4-7 days, and reached normal values for the jejunum after 14-30 days. This increase was accompanied by a simultaneous increase in the number of cells per crypt column up to 130% of values in jejunum and ileum *in situ*. The percentage of labeled crypt cells, after labeling with ^{3}H-thymidine, and the relative size of the proliferative cell compartment in the crypt in the transposed ileum did not differ from values in the ileum *in situ* at any time interval after surgery. The total proliferative activity per crypt, which was determined by scintillation counting of isolated crypts after ^{3}H-thymidine labeling, increased twofold from 7 days after surgery. Cell migration studies showed that the increase in the number of villus cells was probably not caused by a change in the life span of the epithelial cells. The increase in the number of villus cells in ileal epithelium after transposition to proximal jejunum appears to be brought about by an enlargement of the crypt, while the relative size of the proliferative cell compartment in the crypt remains unchanged.

5473 SIMPLE METHOD FOR THE PREPARATION OF SINGLE CELL SUSPENSIONS FROM NORMAL AND TUMOROUS RAT COLONIC MUCOSA. (Eng.)

Perret, V.; Lev, R.; Pigman, W. (New York Medical Coll., Valhalla, NY 10595). *Gut* 18(5):382-385; 1977.

A procedure for obtaining viable single cell suspensions from young Fisher rat colonic epithelium by using phosphate buffered saline containing 0.2 M mannitol is described. The method, which requires antibiotic treatment but no prior enzyme treatment provides undamaged cells in high yield within 1 hr The procedure was also applied to neoplastic rat colonic tissue, which had been induced by repeated intrarectal infusion of *N*-methyl-*N*-nitrosourea. C parison between normal and neoplastic cells showed that neoplastic cells had a higher nucleus:cytoplasm ratio and a higher metabolic activity. The use of mannitol supplement for prolonged viability in both normal and neoplastic cell cultures is recommended.

5474 MORPHOLOGICAL STUDIES OF CHEMICALLY INDUCED COLON TUMORS IN HAMSTERS. (Eng.)

Winneker, R. C.; Tompkins, M.; Westenberger, P.; Harris, J. (Dept. Physiology and Biophysics, Univ Illinois, Urbana, IL 61801). *Exp. Mol. Pathol.* 27(1):19-34; 1977.

The progressive histopathological changes in the colons and livers of 48 hamsters subjected to weekly s.c. injections of 1,2-dimethylhydrazine (DMH) for 21 weeks were studied by sacrificing animals on a weekly basis. After 15 injections, (20 mg/kg), all remaining animals (n=17) displaye neoplastic lesions of the colon. Of the 17 animals, 10 exhibited adenocarcinomas *in situ*. Of the remaining seven which showed invasive adenocarcinomas of the colon, five animals also revealed metastatic lesions in the liver. Tumor pr gression followed the course of colonic enteritis (5 weeks), focal atypias (7 weeks), glandular dys plasias (10-14 weeks), carcinomas *in situ* (15 wee and invasive adenocarcinomas (17 weeks). Ultrastructural features of both tumors and normal ham ster colon were studied. Alterations in nuclear contour, size of intercellular spaces, and shape and density of luminal microvilli were noted. These studies show that the toxic effect of DMH o the liver is pronounced and is associated with certain progressive morphological changes.

5475 ISCHAEMIC COLITIS IN THE EXPERIMENTAL ANIMAL. I. COMPARISON OF THE EFFECTS ACUTE AND SUBACUTE VASCULAR OCCLUSION. (Eng.)

Matthews, J. G. W.; Parks, T. G. (Dept. Surgery, Queen's Univ., Belfast, Northern Ireland). *Gut* 17(9):671-676; 1976.

A study was undertaken to compare the effects on the colon of acute vascular interruption with th effects of a more gradual occlusion of the same vessels. Two group of dogs were studied, having either acute ligation of the common colic and caudal (inferior) mesenteric arteries (group I) acute ligation of the common colic artery and gr ual occlusion of the caudal mesenteric artery (group II). In group I, acute ligation caused ischemic colitis in all five dogs tested, but no died. Within the first 36 hr of the acute ligat bleeding was present in two dogs and diarrhea an sigmoidoscopy changes in all the dogs ($p<0.005$). The most prominent pathological features, mucosa edema and ecchymoses, were present sometimes as early as 4 hr after the acute vascular ligation.

Edema and swelling of the mucosal folds led to the formation of narrow grooves between adjacent folds which, when filled with barium, gave a saw-tooth margin to the bowel. Thumb-printing was demonstrable 12-24 hr after acute ligation and pseudotumor formation usually followed within the next 24-48 hr. Regression of the endoscopic appearance to normal was reported within 10-21 days. In group II, the dogs had no sign of diarrhea or bleeding. There was no evidence of ischemic colitis over a 2- to 3-week period. These findings suggest that the collateral blood vessels are capable of providing adequate circulation to the dog's colon, but that they do not open up rapidly enough to prevent ischemic change when the two major arteries are acutely ligated.

5476 ISCHAEMIC COLITIS IN THE EXPERIMENTAL ANIMAL. II. ROLE OF HYPOVOLAEMIA IN THE PRODUCTION OF THE DISEASE.

(Eng.) Matthews, J. G. W.; Parks, T. G. (Dept. Surgery, Queen's Univ., Belfast, Northern Ireland). *Gut* 17(9):677-684; 1976.

A study was undertaken to investigate the role of reduced perfusion pressure in the etiology of ischemic colitis. Three groups of five dogs each were studied: group 1, hypovalemia alone, induced by the removal of 30% of the dog's blood volume; group 2, acute ligation of the common colic artery and gradual occlusion of caudal mesenteric artery followed 4 weeks later by hypovolemia; and group 3, acute ligation of the caudal mesenteric artery with hypovolemia induced immediately after the ligation procedure. Hypovolemia alone did not lead to ischemic colitis but may lead to a 50-75% reduction in mesenteric blood flow without producing any signifi-cant change in the systemic blood pressure. In group 2 all five animals developed ischemic colitis. Microvascular thrombosis was a common pathological ntity and was associated with the formation of esicles and their subsequent ulceration and hemorrhage (diarrhea and sigmoidoscopy changes, $p<0.005$). n group 3, the affected segment was localized, and leeding was profuse (diarrhea and bleeding, <0.02; sigmoidoscopy changes, $p<0.005$). In animals with severe ischemic involvement of the colon, "thumbprinting" and pseudotumors became demon-trable. These findings suggest that states of low lood flow in the presence of previous arterial onstriction or blockage may lead to sufficient re-uction in mesenteric perfusion for intestinal schemia to develop.

477 BENEFICIAL EFFECT OF ALCOHOL IN EXPERIMENTAL DUMPING SYNDROME IN DOGS: RELATION O BLOOD KININS.

(Eng.) Chaimoff, C.; Edery, H.; braham, S.; Gassner, S. (Beilinson Hosp., Petah kva, Israel). *Isr. J. Med. Sci.* 13(6):617-620; 977.

e influence of ethanol on experimentally induced mping syndrome (DS) was studied in dogs, and rticular attention was paid to its relation to e level of blood kinins. Shortly after the tra-intestinal infusion of a 50% glucose solution 50 ml), somatic symptoms (salivation, rhinorrhea, diarrhea, vomiting) and behavior disturbances occurred in all four dogs tested. When 10-12 ml of brandy (40% ethanol) were infused intra-intestinally 15-20 min before glucose administration, only mild symptoms of DS were observed in all five animals studied. Only mild symptoms of discomfort were noted in three dogs given glucose and brandy simultaneously. No abnormal changes were noted in dogs given brandy alone. No kinin activity was found in control blood samples or in those obtained after the administration of brandy alone or brandy together with glucose. Concomitant with the appearance of DS in the animals that received glucose alone, plasma kinin activity ranging from 0.4 to 1.6 ng/ml was detected in the first samples (15 min after infusion) of arterial and venous blood. The kinin level gradually increased in the subsequent blood samples (20 and 25 min) and reached a peak concentration of 50 ng/ml. In three of the five dogs that received brandy before glucose no kinins were found, whereas in the other two dogs 50 ng/ml were found in the second and third venous samples. The results suggest that a small amount of ethanol, drunk before meals, may be beneficial in alleviating DS symptoms in man, probably by interfering with the kinin system.

5478 ENDOSCOPIC LASER TREATMENT. II. COMPARISON OF THE EFFICACY OF HIGH AND LOW POWER PHOTOCOAGULATION IN CONTROL OF SEVERELY BLEEDING EXPERIMENTAL ULCERS IN DOGS.

(Eng.) Silverstein, F. E.; Protell, R. L.; Piercey, J.; Rubin, C. E.; Auth, D. C.; Dennis, M. (Dept. Medicine, RG-20, Univ. Washington, Seattle, WA 98195). *Gastroenterology* 73(3):481-486; 1977.

The coagulative efficacy of a "high power" argon laser that delivers 6.5 ± 1.0 watts (W) was compared in dogs to that of a "low power" argon laser that delivers 1.0 ± 0.1 W. The wave-guide angle of divergence was 8 degrees. For the high power laser, the distance between the wave-guide tip and the mucosa was 1.0-1.5 cm with a delivered power density range of 160-487 W/cm^2. For the low power-laser, the distance between the tip and mucosa was 0.7-1.3 cm with a power density of 35-146 W/cm^2. Group A consisted of acute experiments in six heparinized dogs in which 51 standard-sized acute gastric ulcers extending into the submucosa were made at laparotomy via a large gastrotomy. Ulcer bleeding rates were quantified into three categories of severity. Within each category, ulcers were randomized to high power, low power, or untreated control. All 19 low power-treated ulcers and 16 untreated controls continued bleeding; 13 of 16 high power-treated ulcers stopped bleeding completely. Representative ulcers were examined histologically. Group B consisted of chronic experiments on 31 ulcers in 7 unheparinized dogs. These ulcers were either treated with high power or left as untreated controls. Dogs were killed and the ulcers were examined histologically at 7, 14, and 28 days. Only rarely did the laser injury penetrate into the muscularis externa. There were no perforations. By 14 days, all lesions were covered with normal surface epithelium. These data encourage further development of approx 7.0 W argon laser photocoagulation for eventual clinical use in man.

5479 THE EFFECT OF PORTACAVAL SHUNT ON THE ACTIVITY OF THE MITOCHONDRIA AND THE ABSORPTION OF GLUTAMATE IN RAT BRAIN.

(Ita.) Vassanelli, P.; Garbin, L. (Istituto di Patologia Speciale Chirurgica e Propedeutica Clinica, Universita di Padova, Padova, Italy). *Acta Chir. Ital.* 31(2): 287-293; 1975.

A study was made of the effect of portacaval shunt on mitochondrial activity and glutamate absorption in the rat brain. Male Sprague-Dawley rats were given a portacaval shunt and divided into two groups. One group was sacrificed 1 month and the other 12 months following surgery. ^{14}C-labeled glutamic acid was given i.p. 5 and 10 min before sacrifice. Glutamic acid was separated from other amino acids by paper chromatography and radioactivity was determined by liquid scintillation counting. Mitochondrial activity, as measured by the utilization of succinate, glutamate, and α-ketoglutarate, was not affected by the portacaval shunt. Uptake of ^{14}C-glutamate was markedly enhanced in animals that received the shunt. The major portion of the ^{14}C-label was present in γ-amino butyric acid (GABA). The enhanced uptake of glutamic acid appears to be directly correlated with increased production of GABA following portacaval shunt operations.

5480 STRUCTURE OF HEPATITIS B DANE PARTICLE DNA AND NATURE OF THE ENDOGENOUS DNA POLYMERASE REACTION.

(Eng.) Landers, T. A.; Greenberg, H. B.; Robinson, W. S. (Univ. Texas Medical Sch., Houston, TX 77030). *J. Virol.* 23(2):368-376; 1977.

The circular DNA of hepatitis B Dane particles was analyzed by electrophoresis before and after a polymerase reaction and after digestion by restriction endonuclease or single-strand-specific endonuclease S1. The unreacted molecules extracted from the particles were electrophoretically heterogeneous, and treatment with S1 nuclease produced double-stranded linear DNA ranging in length from 1,700 to 2,800 base pairs (bp). After an endogenous DNA polymerase reaction, two discrete species of DNA molecules were found: a circular form and a linear form 3,200 bp long. The reaction resulted in a population of molecules with an elongated and more homogeneous double-stranded region. These results suggest that the circular molecules in Dane particles have single-stranded regions of varying lengths that are made double stranded during the DNA polymerase reaction. The endogenous DNA polymerase was found to initiate apparently at random in a region spanning more than a third of the molecule. Analysis of restriction endonuclease cleavage fragments of the fully elongated DNA revealed that although the molecules were of a uniform length, they were somewhat heterogeneous in sequence. The sum of the sizes of the 10 major endonuclease *Hae* III-generated fragments, detected by ethidium bromide, was 3,880 bp. Two additional fragments (B and G) detected by autoradiography after an endogenous DNA polymerase reaction with ^{32}P-labeled deoxynucleoside triphosphates made the total 4,910 bp. The biological utility of a circular DNA that is single stranded over one-third of its length and a virion enzyme that closes the single-stranded region for a virus such as hepatitis B virus is unclear; such feature have not been described for other viruses.

5481 FOREIGN SERUM-INDUCED PANCREATITIS IN MICE. II. SECRETORY DISTURBANCES OF ACINAR CELLS.

(Eng.) Nevalainen, T. J.; Fowlie, F. E.; Janigan, D. T. (Dept. Pathology, Dalhousie Univ., Halifax, Nova Scotia, Canada). *Lab. Invest* 36(5):469-473; 1977.

An investigation was undertaken in mice to study the mechanism of granule accumulation, the increas in granule enzyme activities, and the relation of these phenomena to the development of acinar c death following necrosis after one i.p. injection of foreign serum (0.85 ml). Enlargement of the pancreas was reported due to an increase in the number of zymogen granules in non-necrotic cells. Three hours after the injection, pancreatic amyla activity was 116.6 ± 8.8 units/mg wet weight in r pients of fresh serum as compared to 80.7 ± 4.0 U wet weight of heated serum recipients ($p=0.01$) an continued to increase in recipients of fresh seru for the 12-hr period studied ($p=0.001$). These ch were coupled with a progressive decrease in the s tory response to pilocarpine (5 mg/ml) and were p ceeded by significant disturbances in the pancrea tissue concentrations of sodium (increased 3 hr a injection, $p<0.001$) and potassium (decreased 3 hr after injection, $p<0.001$). An injury mechanism w reported which permits granule formation to proceed in the face of impaired granule exocytosis. The granule secretory process is reported to be more sensitive than the zymogen synthesis process to the serum injury mechanism. Acinar cell necrosis was maximal by 12-15 hr. It is concluded that increase in granules is neither the primary determinant nor the initiator of acinar cell deat It is suggested that disturbance in plasma membra functions leads to acinar cell death.

5482 EXPERIMENTAL PANCREATICODUODENAL ALLOTR PLANTATION: STUDIES IN THE UNIMMUNOSUP PRESSED PIG.

(Eng.) Jensen, S. L.; Nielsen, O. V.; Kuhl, C.; Petri, M. (Rigshospitalet, Blegdamsvej 9, DK-2100 Copenhagen, Denmark). *Dan. Me Bull.* 24(2):55-60; 1977.

A study was undertaken to investigate pancreatico duodenal allotransplantation in unimmunosuppresse pigs and the insulin secretion of the allograft. Healthy white Landrace pigs were used, and donor and recipient were from the same breed. Total pa createctomy was always performed in the recipient pig following one of three protocols. In group 1 (n=10), total pancreatectomy was performed immediately after pancreaticoduodenal grafting. All pigs in this group died within 15 days (mean survival time 4.6 days). In group 2 (n=12), total pancreatectomy was performed 1 week after pancreaticoduodenal grafting. The mean survival tim of these pigs was 34.0 days (range 11-98 days). Normal pancreatic tissue appearance was reported on gross and microscopic examination in all pigs that did not die from vascular thrombosis or rejection. Hyperinsulinemia persisted in all recipients until death or rejection of the graft. Pigs in group 3 (n=5) were subjected to total pancreatectomy alone and served as the control group. These pigs developed hyperglycemia and severe ketoacidosis; their mean survival time was 3.0 days. Plasma from these pigs contained 5-10 μU/ml serum insulin before death. Residual pancreatic tissue was not identified at autopsy. The pig is a useful experimental animal for the study of pancreaticoduodenal transplantation.

5483 CANINE HISTIOCYTIC ULCERATIVE COLITIS: AN ULTRASTRUCTURAL STUDY OF THE EARLY MUCOSAL LESION. (Eng.) Gomez, J. A.; Russell, S. W.; Trowbridge, J. O.; Lee, J. (Scripps Clinic and Res. Foundation, 476 Prospect St., La Jolla, CA 92037). *Am. J. Dig. Dis.* 22(6):485-496; 1977.

DIAGNOSTIC PROCEDURES

510 ^{13}C-TRIOCTANOIN: A NONRADIOACTIVE BREATH TEST TO DETECT FAT MALABSORPTION. (Eng.)

atkins, J. B.; Schoeller, D. A.; Klein, P. D.;
tt, D. G.; Newcomer, A. D.; Hofmann, A. F. (Chil-
ren's Hosp. Medical Center, 300 Longwood Ave.,
ston, MA 02115). *J. Lab. Clin. Med.* 90(3):422-
30; 1977.

detect fat malabsorption in children and in women
child-bearing age without radiation hazard, the
e of trioctanoin labeled with the stable, non-
dioactive isotope ^{13}C was inaugurated and valida-
d for use in a CO_2 breath test. The validation
sts with both ^{14}C- and ^{13}C-trioctanoin were con-
cted in 14 adult patients with varying degrees
fat malabsorption. The labels were excreted at
arly identical rates (r=0.97). After estab-
shment of dose requirements and measurement of
dogenous $^{13}CO_2$ production rates, nine children
ed 3 months to 5 yr were evaluated for fat mal-
sorption. The results obtained with the ^{13}C-tri-
tanoin breath test were compared to those ob-
ined by a quantitative 72 hr fat balance study.
e cumulative excretion of $^{13}CO_2$ by 2 hr was 25 ±
5% of the dose in patients with normal fat ab-
rption and provided a clear differentiation
<0.001) from the 3.5 ± 2.5% of the dose excreted
those with steatorrhea due to untreated pan-
eatic insufficiency resulting from cystic fibrosis.
ak $^{13}CO_2$ levels occurred at 1.5 hr in both groups
th some overlap. Addition of exogenous pancreatic
zymes improved fat absorption and increased $^{13}CO_2$
cretion fourfold. The correlation between the per-
nt of fat intake excreted and the cumulative
O_2/mmol CO_2 excreted by 3 hr was very good (r=
.88) in all patients. These data indicate that
e ^{13}C-trioctanoin breath test provides accurate
tection of fat malabsorption in children with
ncreatic insufficiency. This noninvasive tech-
que is more convenient than 72 hr stool collec-
n and permits safe and sensitive metabolic
dies in children without exposure to radiation.

1 ELASTOLYTIC ACTIVITY OF THE HUMAN DUODENAL CONTENT. (Ger.)

Fric, P.; Slaby, J.;
afirek, E.; Malis, F. (II. Forschungslaboratorium
Gastroenterologie der Karlsuniversitat, Karlovo
. 32, 12111 Prague 2, Czechoslovakia). *Dtsch.
Verdau. Stoffwechselkr.* 36(3/4):239-244; 1976.

rease in duodenal elastase output following stim-
tion with pancreozymin (75 U, i.v.) and secretin
U, i.v.) was determined in 54 patients using
cinyltrialanine-*p*-nitranilide as substrate.
average elastase output during the 80 min after
mulation was 142.1 ± 21.4 μM in 24 controls,
2 ± 6.8 μM in 8 patients with functional insuf-
iency due to organic pancreatic changes, and 86.1
.7 μM in 24 patients with decreased amylase out-
. Two elastolytic fractions, possibly represent-
different activation phases of the elastase,
e found in the duodenal content by gel electro-
resis and DEAE-sephadex chromatography. The
ctions had the same molecular weight and K_m
,500 and 0.45 mM, resp.), but differed in their
ement and elution through different salt concentrations and in their behavior to synthetic and natural substrates.

5512 SIGNIFICANCE OF BACTERIAL STEROID DEGRADATION FOR THE ETIOLOGY OF LARGE BOWEL CANCER. VII. METHODOLOGY OF THE IDENTIFICATION OF DEGRADATION PRODUCTS OF BILE ACIDS. (Ger.)

Slemrova, J.; Edenharder, R. (Hygiene-Institut der Universitat, D-6500 Mainz 1, Hochhaus am Augustusplatz, W. Germany). *Zentralbl. Bakteriol.* [*Orig. B*] 164(3): 235-249; 1977.

The bacterial transformation products of cholic, chenodeoxycholic, and deoxycholic acids were identified by thin-layer and gas chromatography and mass spectrometry. *Bacteroides thetaiotaomicron* strains were used. The mean error of retention factors obtained with thin layer chromatography was too large to make a clear distinction between some bile acid transformation products with similar chromatographic properties. The influence of relative air humidity was decisive. This effect became apparent only after a certain threshold value was exceeded. A dependence of the retention factors on temperature and some mutual interferences between bile acids in mixtures were demonstrated. The gas chromatographic identification of trimethylsilyl ethers of bile acid methyl esters was complicated by methylation and silylation artifacts and the insufficient resolution power of packed columns; the gas chromatographic analysis, however, mainly gave correct results. Mass spectrometric identification was found to be the most reliable one. The reference spectra of five silylated bile acid methyl esters (lithocholic, deoxycholic, cholic, apocholic, and 3α,12α-dihydroxy-7-oxo-5β-cholanoic acid) and one silylated bile acid, trimethylsilyl ester, are presented. Combined gas chromatography-mass spectrometry is an analytical method well suited to study the bacterial transformation products of bile acids.

5513 SERUM IMMUNOGLOBULIN LEVELS IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Ger.)

Sailer, D.; Ullmann, B.; Berg, G. (Medizinische Klinik mit Poliklinik, Universitat Erlangen-Nurnberg, Krankenhausstr. 12, 8520 Erlangen, W. Germany). *Dtsch. Med. Wochenschr.* 101(33):1214-1217; 1976.

IgA, IgG, and IgM levels were determined quantitatively by radial immunodiffusion in 50 patients with ulcerative colitis and 41 patients with Crohn's disease to establish possible diagnostic or prognostic value of disease-specific immunograms. In comparison to healthy controls, a slight decrease in IgG, IgA, and IgM was found in ulcerative colitis. In Crohn's disease, IgG levels were normal, IgA was increased by 37.3%, and IgM was decreased by 37%. Typical immunograms appear to be valuable in the differential diagnosis of Crohn's disease.

5514 INTESTINAL ALKALINE PHOSPHATASE IN THE DIAGNOSIS OF LIVER DISEASE. (Eng.)

Warnes, T. W.; Hine, P.; Kay, G. (Manchester Royal

Infirmary, Manchester, England). *Gut* 18(4):274-278; 1977.

The value of the newer techniques of isoenzyme analysis in the diagnosis of liver disease was evaluated in 76 patients, and the question of whether they are helpful in differentiating an intrahepatic from an extrahepatic cause of jaundice was studied. Alkaline phosphatase isoenzymes were studied by acrylamide gel disc electrophoresis in 15 patients with an extrahepatic lesion, 53 with an intrahepatic lesion, and 8 patients who had features of both intra- and extrahepatic disease. No intestinal band was found in the 15 cases of extrahepatic liver disease, in marked contrast to the patients with intrahepatic lesions in whom an intestinal band was found in 45% of cases. The intrahepatic group was heterogeneous, a high incidence of intestinal bands being found in patients with liver cirrhosis. It is concluded that where a raised serum alkaline phosphatase is found in a patient with jaundice, and a gut band is present on electrophoresis, the lesion is likely to be intrahepatic.

5515 COMPUTED TOMOGRAPHY OF THE LIVER. (Eng.) Stephens, D. H.; Sheedy, P. F., II; Hattery, R. R.; MacCarty, R. L. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Am. J. Roentgenol.* 128(4):579-590; 1977.

Experience with abdominal computed tomography (CT) in more than 600 liver examinations over a 10-month period using a system fast enough to eliminate respiratory motion is reported. CT was highly accurate, but not infallible, in detecting and defining space-occupying lesions, but was less helpful in detecting diffuse hepatic disease. Space-occupying lesions in the liver were detectable by CT when their attenuation of the x-ray beam differed appreciably from the attenuation by the surrounding tissue. The great majority of all intrahepatic masses discovered, whether solid or cystic, neoplastic or inflammatory, were of diminished radiographic density. Exceptions to this were lesions containing calcium or extravasated blood. In nine patients with clinically apparent cirrhosis, no outstanding alteration in hepatic density was seen on CT, although in two, the liver parenchyma had a slight nonspecific inhomogeneity. The diffuse process with the most impressive CT appearance was fatty infiltration, a finding noted in five patients. In this condition, the diminished parenchymal density was easily recognized by comparing it with the density of the spleen. The intrahepatic vessels stood out as relatively dense structures against the radiolucent background of hepatic parenchyma. In bile duct obstruction, the dilated ducts were easily recognized in most patients because of the low density of bile. Often, information about the obstructing lesion was also obtained. Masses in the porta hepatis and head of the pancreas were found in 7 of 13 patients with dilated ducts. In two other patients, the presence of a dilated pancreatic duct associated with dilated bile ducts established the site of obstruction as beyond the confluence of the common bile duct and pancreatic duct. The proper clinical role of CT in relation to other diagnostic methods, especially nuclear imaging, remains to be established.

5516 HEPATIC LYMPHOGRAPHY. (Jpn.) Sako, M. (Kobe Univ. Sch. Medicine, Kobe, Japan). *Nippon Acta Radiol.* 35(9):733-745; 1975.

Indirect lymphography of the liver using a new water soluble contrast medium consisting of 65% meglumine iodamide and 2% nonionic surfactant (polyoxyethylene hydrogenated castor oil) was carried out in dogs and in patients with liver cirrhosis, chronic hepatitis, and obstructive jaundice. The contrast medium (5 ml, 2 ml/min) was injected into the livers of anesthetized dogs. Several lymphatic vessels were well opacified. No significant cellular changes were observed. In 18 patients, 10-15 ml of the contrast medium was injected percutaneously into the liver parenchyma under local anesthesia. Several lymphatics were opacified, extending to the hilus; the lymphatics were tortuous and were interlaced, which distinguished them from the vascular system. Lymphographic visualization was obtained in all cases, and the hilar lymph node was opacified in five cases In the six patients with cirrhosis, the lymphatic vessels appeared irregular and tortuous; there was a characteristic ripple-like appearance, which was considered to be a distinctive feature of liver cirrhosis. The lymphatic vessels were irregular, and the margin was rigid in only two of the six cases of chronic hepatitis. In six patients with obstructive jaundice, the lymphatic vessels were mildly dilated and they had a beaded appearance. The patients experienced no untoward effects from this procedure. Hepatic lymphography using the new contrast medium demonstrates characteristic patterns in different liver diseases; this method may be a valuable adjunct to other examinations in the diagnosis of liver diseases.

5517 REFINEMENTS IN CHIBA NEEDLE TRANSHEPATIC CHOLANGIOGRAPHY. (Eng.) Ferrucci, J. T., Jr.; Wittenberg, J. (Massachusetts General Hosp and Harvard Medical Sch., Boston, MA 02114). *Am. J. Roentgenol.* 129(1):11-16; 1977.

Present techniques of Chiba needle transhepatic cholangiography, intraprocedure observations, and special interpretive considerations based on a series of 100 consecutive examinations are reviewed The established safety margin of this technique now permits up to 15 needle passes to obtain a cholangiogram; thus, success rates of duct opacific tion presently approach 100%. Special phenomena related to the small caliber of the needle include duct filling from "invisible" radicles, perivenous or periductal dissection of contrast, and pseudolesions in an incompletely decompressed stagnant bile column. In patients with suspected biliary obstruction, either i.v. cholangiography or gray scale ultrasonography (and/or computer tomography) should be used as the initial noninvasive study, as indicated by the serum bilirubin level. The

robability of duct opacification by i.v. cholangio-
graphy diminishes rapidly above total bilirubin
evels of 3 mg/100 ml, and thus cross-sectional
maging studies, radionuclide examinations, and
ngiography play only a secondary role. Direct
eedle cholangiography is still recommended for
recise delineation of the level and nature of
he obstructing lesion prior to surgery.

518 IMMUNOCHEMICAL STUDIES ON MACROMOLECULAR
GASTRINS: EVIDENCE THAT "BIG BIG GASTRINS"
RE ARTIFACTS IN BLOOD AND MUCOSA, BUT TRULY PRESENT
N SOME LARGE GASTRINOMAS. (Eng.) Rehfeld, J. F.;
chwartz, T. W.; Stadil, F. (Inst. Medical Biochem-
stry, Univ. Aarhus, DK-8000 Aarhus C, Denmark).
astroenterology 73(3):469-477; 1977.

he question of whether macromolecular gastrin--ear-
ier designated "big big gastrin" (BBG)--is present in
lood and tissue was evaluated by gel and affinity
hromatography monitored radioimmunochemically. Gel
hromatography on small Sephadex G-50 columns (10 by
00 mm) of serum from eight normal fasting subjects
onfirmed that apparent gastrin immunoreactivity is
luted in the void volume. However, in contrast to
he established serum gastrins (components I to IV),
he apparent serum BBG was not removed by affinity
hromatography. The amount of apparent BBG was
elated to the amount of proteins present in the
id volume fractions and to the ability of serum
oteins to interfere with the binding affinity of
ree different antisera used. Gel chromatography
Sephadex G-50 columns of antral, duodenal, and
junal extracts revealed gastrin in the void vol-
e only when large amounts of extracts were applied
the columns. By refiltration of these void vol-
e fractions the apparent BBG disappeared, and gas-
in immunoreactivity was now eluted corresponding
components I, II (gastrin-34 or "big" gastrin),
d III (gastrin-17 or "little" gastrin). In con-
ast to these findings, an extract of a large
strinoma, previously used to substantiate the
ture of BBG, contained a number of gastrin macro-
lecules with apparent molecular masses ranging
om 30,000 to 100,000 daltons. These gastrins,
fined as BBG by their elution in the void volume
Sephadex G-50 columns, were removed by affinity
romatography using antibodies specific for the
rboxyl terminal sequence of gastrin-17 from buffer
serum solutions. Elution in urea gradient on
hadex G-50 columns of extracts from three gas-
inomas additional disclosed BBG in one tumor.
results indicate that there are no detectable
e macromolecular gastrins in serum and non-neo-
stic gastrointestinal mucosa. The apparent BBG
attributable to interference in the gastrin assay
normal serum proteins or to weak noncovalent
tein-binding of smaller gastrins. In contrast,
e gastrin macromolecules consisting of gastrin-
covalently coupled in its amino-terminus to pro-
ns of varying length are present in detectable
unts in some large gastrinomas.

9 BASIC PRESSURE IN THE PANCREATIC DUCT AND
IN THE BILE DUCT: RESULTS FROM 50 STAND-
IZED DUODENOSCOPIC TRANSPAPILLARY PRESSURE MEASUREMENTS. (Ger.) Weiss, H. D.; Kramann, B.; Wuttke, V.; Anacker, H. (Institut fur Rontgendiagnostik, Ismaninger Strasse 22, D-8000 Munchen 80, W. Germany). *Med. Klin.* 72(12):519-523; 1977.

Duodenoscopic transpapillary pressure measurements of the common bile duct and pancreatic duct were made in 20 and 70 patients, resp., following premedication with atropine (0.5 mg i.m.), triflupromazine (10 mg i.m.), and meperidine (50 mg i.v.). Normal findings were noted on 42 occasions, whereas marked chronic recurrent pancreatitis was found twice, suspicion of chronic pancreatitis (3 times), papillary stenosis (1), pancreas carcinoma (1), and mucovisidosis (1). As a result of the 20 measurements in the common bile duct, gallstones were found in 8 patients, benign bile duct stenoses in 3, and normal findings in 9. The mean basic pressure values of the common bile duct were 12.0 cm H_2O (7.3-17.0 cm H_2O). Almost normal pressure was seen in cases of bile duct concretions (11.7 cm H_2O). However, a mean pressure of 32 cm H_2O was noted in one patient with infiltrating carcinoma of the pancreas head. The mean pressure in the pancreatic duct was 22.2 cm H_2O (range 9.6-37.0 cm H_2O). However, in two patients with marked chronic pancreatitis and one with pancreatic carcinoma, the secretion pressure was considerably diminished. The mean pressure values in the duodenum were considerably lower than in the common bile duct or the pancreatic duct and ranged from 0.6 to 10.9 cm H_2O. Different undulation patterns were detected in both ducts including slight undulations (slow pressure changes with constant average pressure) and coarse undulations (rapid fluctuating pressure changes). The significance of the findings for the physiology and pathophysiology of the pancreatic and biliary duct systems and for the possible detection of excretory pancreatic insufficiency or stenosis of the pancreatic duct system are also discussed.

5520 DIAGNOSTIC IMPORTANCE OF CHANGES IN CIRCULATING CONCENTRATIONS OF IMMUNOREACTIVE TRYPSIN. (Eng.) Elias, E.; Redshaw, M.; Wood, T. (Royal Free Hosp., London, England). *Lancet* 2(8028): 66-68; 1977.

A specific and sensitive radioimmunoassay (RIA) was developed that makes possible the determination of serum or plasma trypsin concentrations, despite the presence of trypsin inhibitors, which have invalidated previously available enzymatic techniques. The assay was used in a preliminary series of 187 patients in whom the condition of the pancreas was known. The assay was most precise at about 300 μg trypsin standard Ag5/1 of serum, a value comparable with the mean in 76 healthy volunteers (273 μg/l) and in 20 hospital patients with nonpancreatic disease (266 μg/l). Markedly raised concentrations (970-6,500 μg/l) were found in all 14 patients with acute pancreatitis and in 8 patients with chronic renal failure (580-1,360 μg/l). Abnormal concentrations were found in 11 of 16 patients (69%) with pancreatic cancer (8 high, 3 low) and in 15 of 23 patients (65%) with chronic pancreatitis (3 high, 12 low). The 17 patients with jaundice had normal or marginally lower than normal concentrations, unless pancreatic disease or common duct gallstones were present. Measurement of serum trypsin at an early stage may simplify and shorten the sequence of tests undergone by many patients to obtain a definitive diagnosis in pancreatic disease.

5521 ARTERIOGRAPHY IN THE EVALUATION OF PANCREATIC PSEUDOCYSTS. (Eng.) Levin, D. C.; Eisenberg, H.; Wilson, R. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *Am. J. Roentgenol.* 129(2):243-248; 1977.

A policy of limiting preoperative diagnostic imaging of pancreatic pseudocysts to barium studies, sonography, or computer tomography is discussed; this policy will result in failure to detect frequently associated lesions, which may only be appreciated by arteriography and that radically alter both the prognosis and surgical approach. These associated lesions include: pseudoaneurysms, probably the most common cause of major gastrointestinal hemorrhage in pseudocyst patients; pancreatic carcinoma, a possible etiologic factor leading to formation of the pseudocyst; benign or malignant cystadenomas, which mimic pseudocysts clinically, but can be usually identified arteriographically by prominant neovascularity; and splenic vein obstruction, which can produce extrahepatic portal hypertension and necessitate splenectomy. These complicating lesions have been found to be relatively common. Their preoperative detection is desirable and is best accomplished by arteriography. For this reason, arteriography should be routinely performed in patients suspected of pancreatic pseudocyst.

5522 ^{99m}Tc-PYRIDOXYLIDENE GLUTAMATE, A GALL BLADDER IMAGING AGENT: CHEMISTRY OF PREPARATION AND COMPARATIVE ANIMAL STUDIES WITH ^{131}I-ROSE BENGAL. (Eng.) Chiotellis, E.; Subramanian, G.; McAfee, J. G. (N.R.C. "Democritos," Athens, Greece). *Int. J. Nucl. Med. Biol.* 4(1):21-28; 1977.

GASTROINTESTINAL DISEASES

ESOPHAGUS

557 VALUE AND LIMITATIONS OF THE DETERMINATION OF CARCINOEMBRYONIC ANTIGEN (CEA) N PATIENTS WITH ESOPHAGEAL AND GASTRIC CANCER. Fre.) Chatal, J. F.; Dedieu, P. R.; Lemevel, B. .; Helary, J.; Guihard, D.; Salard, J. L. (Centre ene Gauducheau, 44 Nantes, France). *Bull. Cancer Paris)* 63(4):531-540; 1976.

study was made of the carcinoembryonic antigen (CEA) n 58 patients with histologically diagnosed cancer f the esophagus and 32 patients with cancer of the tomach. A value of 10 ng/ml of serum was selected s the upper limit for CEA levels after evaluations n 127 normal patients. Of the 58 esophageal cancer atients, 40% had CEA levels between 10-20 ng/ml. nly 8.6% had CEA values greater than 20 ng/ml and nly one value was higher than 50 ng/ml. Fifty-hree percent of stomach cancer patients had CEA evels greater than 10 ng/ml. Of these, 23% were reater than 20 ng/ml and 19% were greater than 50 g/ml. CEA values appear to be higher in cases of tomach cancer than esophageal cancer. Values reater than 50 ng/ml in either disease are most ikely to be indicative of metastasis. There appears o be a correlation among CEA titers and location, ge, and histological appearance of the tumors. CEA easurements may be of value in distinguishing be-ween local recurrence and metastasis in certain ypes of cancer.

558· RADIOLOGIC MANIFESTATIONS OF ESOPHAGEAL LYMPHOMA. (Eng.) Carnovale, R. L.; oldstein, H. M.; Zornova, J.; Dodd, G. D. (Hermann osp., Houston, TX 77030). *Am. J. Roentgenol.* 28(5):751-754; 1977.

he cases of eight patients with esophageal lymphoma re summarized, and the spectrum of radiologic ppearances is presented. The series included five en and three women ranging in age from 30 to 71 yr. our patients had histiocytic lymphoma, two had ymphocytic lymphoma, one each had undifferentiated ymphoma and Hodgkin's disease. Four had dysphagia, hile the remaining patients had no symptoms refer-ble to the esophagus. All patients had gastro-ntestinal involvement, and the stomach was affected n all cases. The most common radiologic appearance 5 cases) was involvement of the distal portion of he esophagus in association with contiguous nvolvement of the gastric fundus; this was accom-anied by nodularity and nonobstructive narrowing f the distal esophagus. Other appearances were an lcerated mass in the proximal third of the thoracic sophagus, multiple submucosal nodules throughout he lower two-thirds of the thoracic esophagus occurring in the only patient without involvement f the gastroesophageal junction), and a pattern imulating esophageal varices. The radiologic eatures in these patients are similar to those ccurring elsewhere in the gastrointestinal tract.

5559 THE RELATIONSHIP BETWEEN SERUM IRG LEVELS AND LES PRESSURE UNDER VARIOUS CONDITIONS. (Eng.) Siewert, R.; Weiser, H. F.; Lepsien, G.; Jennewein, H. M.; Waldeck, F.; Arnold, R.; *et al.* (Oberarzt der Universitats-Klinik fur Allgemeinchirurgie, Gosslerstrasse 10, D-3400 Gottingen, W. Germany). *Digestion* 15(3):162-174; 1977.

To investigate whether there is any correlation between fasting gastrin level and resting pressure of the lower esophageal sphincter (LES), both values were measured in five groups of patients: (1) 15 patients with manometrically verified gastro-esophageal reflux with pentagastrin-stimulative LES and 15 patients with nonstimulative LES, (2) 20 patients with manometrically and radiologically verified achalasia, (3) 20 patients with hypogastrinemia (fasting gastrin level, 18 pg/ml), (4) 10 patients with hypergastrinemia (fasting gastrin level, 150 pg/ml), and (5) a control group of 20 healthy volunteers. No correlation between fasting immunologically-reacting gastrin (IRG) levels and LES resting pressures could be made in subjects with an undisturbed LES (20 in control group, 15 reflux patients with pentagastrin stimulative LES, and 20 patients with hypogastrinemia). After food ingestion, a short phase of LES pressure increase (from 13.5 ± 1.5 to 21.7 ± 3.8 mm Hg) was observed during the increasing phase of gastrin level, but no correlation was reported in individual control subjects. In groups of patients with LES insufficiency and reflux esophagitis, the LES pressures were lower (7.8 ± 1.4 mm Hg) than those of the control group (13.5 ± 1.5 mm Hg), while the fasting serum IRG levels were normal (34.8 ± 16.6 pg/ml). In six patients with hypergastrinemia, the fasting IRG levels (171.8 ± 38.4 pg/ml) were significantly ($p<0.005$) above those of the control group, but LES pressures were not different. No clear connection in humans between serum gastrin and LES function was shown.

5560 BACTERAEMIA FOLLOWING OESOPHAGEAL DILATATION AND OESOPHAGO-GASTROSCOPY. (Eng.) Stephenson, P. M.; Dorrington, L.; Harris, O. D.; Rao, A. (Princess Alexandra Hosp., Woolloongabba, Brisbane, Queensland 4102, Australia). *Aust. N.Z. J. Med.* 7(1):32-35; 1977.

The potential problem of bacteremia after esophageal dilatation or upper gastrointestinal fiberendoscopy was investigated. Blood cultures were taken immediately prior to the procedure and at 5 and 30 min following the procedure. Swab cultures of the endoscopes and the bougies taken prior to the procedures grew no organisms. Of 11 patients with esophageal stricture or spasm who underwent esophageal dilatation with Hurst's bougies, 5 had significant but asymptomatic streptococcal bacteremia at 5 min, and in 3 of these, the bacteremia persisted 30 min. In an additional patient, *Staph-*

ylococcus albus resistant to penicillin and ampicillin was cultured at 30 min. In two patients with streptococcal bacteremia, identical bacteria were cultured from swabs taken from the bougie after the procedure. No bacteremia was identified in 10 volunteers without esophageal pathology, who underwent passage of the same dilators. After esophagogastroscopy, *Streptococcus viridans* was identified in 1 of 10 patients; this patient underwent gastroscopy because of a duodenal ulcer. Apart from the *Staphylococcus albus* in one of the patients who underwent esophageal dilatation, all organisms cultured were sensitive *in vitro* to penicillin, ampicillin, and cephalosporins. Any of these antibiotics are considered to be suitable for prophylactic use prior to performing esophageal dilatation and upper gastrointestinal endoscopy in "at risk" patients. The risk of bacteremia appears to be much lower after endoscopy than after esophageal dilatation for stricture or esophageal spasm. It is concluded that mucosal trauma is the site of entry of pharyngeal commensals leading to bacteremia.

5561 THE COLUMNAR-LINED ESOPHAGUS--ANALYSIS OF 26 CASES. (Eng.) Robbins, A. H.; Hermos, J. A.; Schimmel, E. M.; Friedlander, D. M.; Messian, R. A. (Veterans Admin. Hosp., 150 S. Huntington Ave., Boston, MA 02130). *Radiology* 123(1):1-7; 1977.

Clinical and radiographic findings are reported in 26 patients with specialized columnar epithelium in the esophagus (Barrett's esophagus). Dysphagia (21 patients) and heartburn and/or regurgitation (20 patients) were the most common clinical features in these patients. Sixteen of 26 patients had radiological evidence of reflux, and 16 of 17 patients had manometrically documented incompetent lower esophageal sphincters. A total of 22 patients had either demonstrable gastroesophageal reflux by oral barium study and/or lower esophageal sphincter pressures below 10-12 mm Hg. Hiatal hernia, stricture in the middle or lower esophagus, ulcers, and minor mucosal abnormalities were found to be variably located. Mucosal irregularity, nodularity, or thickening, indicating superficial ulceration, was reported in 19 patients. It is suggested that Barrett's esophagus is a developmental change that usually occurs consequent to gastroesophageal reflux, with replacement of squamous epithelium by columnar epithelium (without parietal cells), and may be premalignant in nature.

5562 INTRATHORACIC VOLVULUS OF THE STOMACH IN HIATUS HERNIA. REPORT OF SIX CASES. (Fre.) Doutre, L. P.; Perissat, J.; Gouffrant, J. M.; Bobois, J. P.; Grenet, J. (Clinique Chirurgicale A, C.H.U., 311, boulevard du President Wilson, 33200 Bordeaux, France). *Ann. Chir.* 31(6):511-514; 1977.

Intrathoracic volvulus of the stomach was successfully corrected in five of six patients with hiatal hernias. In the first three stages of volvulus (ascension, incarceration, and reducible obstructio the problem was easily approached abdominally. Irreducible obstructions and strangulations necessitated a thoracotomy, which led to a high mortalit (1/2 cases). Preventive surgery is recommended whenever the volvulus reaches the stage of incarceration, even in high risk patients.

5563 PREGNANCY HEARTBURN IN NIGERIANS AND CAUCASIANS WITH THEORIES ABOUT AETIOLOGY BASED ON MANOMETRIC RECORDINGS FROM THE OESOPHAGUS AND STOMACH. (Eng.) Bassey, O. O. (Coll. Medicine Univ. Lagos, P.M.B. 12003, Lagos, Nigeria). *Br. J. Obstet. Gynaecol.* 84(6):439-443; 1977.

The incidence of heartburn during pregnancy in Nigerians was compared with that of Caucasians, and the etiology of heartburn was studied by determining the lower esophageal sphincter pressure in pregnant and nonpregnant women. A study by questio naire of the incidence of pregnancy heartburn in two groups of Nigerians and one group of Caucasian showed an incidence of 9.8% in all Nigerians and 78.8% in Caucasians. The difference was highly significant ($\chi^2=102.75$, $p<0.0001$). An esophageal manometric study of the lower esophageal sphincter in 12 nonpregnant women and in 12 pregnant Nigeria (10 without heartburn and 2 with heartburn) showed that the mean lower esophageal sphincter pressure in the pregnant patients without heartburn was 20.1 ± 7.0 mm Hg and 17.9 ± 7.0 mm Hg in the nonpregnant women. While one pregnant subject withou heartburn had a lower esophageal sphincter, which was partially displaced into the thorax, none of the nonpregnant women had such sphincter displacement. The two pregnant women with heartburn had low resting sphincter pressures, and in both of them, the sphincters were partially in the thorax. It is concluded that pregnancy heartburn is due to the displacement of the lower esophageal sphincter into the negative pressure environment of the thor where the sphincter is less capable of resisting reflux. Pregnancy heartburn is commoner in Caucasians than in Nigerians because the sphincter in nonpregnant Caucasians is often partly intrathora and is more easily displaced completely into the thorax by the pregnant uterus.

5564 CHILDHOOD GASTROESOPHAGEAL REFLUX: NEUROLOGIC AND PSYCHIATRIC SYNDROMES MIMIC (Eng.) Bray, P. F.; Herbst, J. J.; Johnson, D. G Book, L. S.; Ziter, F. A.; Condon, V. R. (Univ. Utah Coll. Medicine, 50 N. Medical Dr., Salt Lake City, UT 84132). *JAMA* 237(13):1342-1345; 1977.

The cases of 13 infants and children (aged 2 mont to 3.5 yr) with proven gastroesophageal reflux (G in whom the initial clinical features suggested a neurologic or psychiatric disorder are presented. Signs of dystonia, especially abnormalities in th posture of the head and neck, were present in 11 patients, irritability in 10, developmental retar ation in 10, and dysphagia in 9. In six infants the occurrence of apparent seizures reinforced th concern that the other symptoms had a primary neurologic basis, leading to the institution of anticonvulsant therapy in four cases. The authors believe that the seizures in all cases represented episodes of reflux, aspiration, and laryngospasm, usually associated with apnea, cyanosis, and stiffening. This sequence may have been responsible for the death of one infant. Pulmonary infiltrates were demonstrated one or more times in 8 of the 13 cases. Three patients were referred to psychiatrists at 3 to 5 yr of age, when explanations for their torticollis, abdominal pain, and irritability could not be found. Symptoms began in early infancy in 10 cases, but accurate diagnosis and proper treatment were not instituted in three patients until 3 to 5 yr of age. The diagnosis of GE reflux, with hiatal hernia in five cases, was made in all cases. Most patients responded to appropriate medical or surgical treatment. The authors believe that the diagnosis of symptomatic GE reflux is often overlooked. The consequences of missed diagnosis or improper treatment are potentially lethal.

5565 CORRELATION BETWEEN MANOMETRIC AND pH TESTS FOR GASTRO-OESOPHAGEAL REFLUX.

Eng.) Stanciu, C.; Hoare, R. C.; Bennett, J. R. Hull Royal Infirmary, Kinston upon Hull, England). *ut* 18(7):536-540; 1977.

o determine which of several diagnostic tests best atches the clinical diagnosis of gastroesophageal eflux, gastroesophageal sphincter pressure measure- ent, short-term pH tests, and 15-hr overnight sophageal pH recording were carried out in 42 ormal subjects and 214 patients with typical reflux ymptoms. The results were compared by multivariate iscriminant analysis. Sphincter pressure measure- ents misclassified 32%, while stressed provocative aneuvers misclassified 14.5%; the best single iscriminator from the overnight pH study was time elow pH 5, which misclassified 13%. However, a ombination of the number of reflux episodes in 15 r with their mean duration reduced misclassifica- ion to 8.8%. Using this function, a boundary etween normal and reflux can be drawn, and the egree of abnormality can be expressed visually as ell as numerically.

566 RHEUMATOID ESOPHAGEAL DISEASE. (Eng.)

Nishikai, M.; Asaba, G.; Homma, M. Dept. Medicine, State Univ. New York at Buffalo, 495 Bailey Ave., Buffalo, NY 14215). *Am. J. astroenterol.* 67(1):29-33; 1977.

e existence of esophageal dilatation in rheumatoid thritis (RA) is reported. Standard posteroanter- r esophagrams were performed in 43 RA patients d in 43 healthy subjects matched with the patients sex and age. The incidence of esophageal dila- ation (esophageal diameter exceeding 30 mm) in RA tients (28%) was significantly higher ($p<0.001$) an that in healthy subjects (0%). The mean esoph- eal diameter in the RA patients was 26.5 ± 14.1 compared with 22.0 ± 8.3 mm for healthy subjects. higher incidence of esophageal dilatation was served in patients with pulmonary fibrosis and patients with s.c. nodules ($p<0.01$, $p<0.05$, resp.). The incidence of esophageal dilatation in 3 patients with pulmonary fibrosis was 100% compared with 23% for 40 patients without pulmonary fibrosis. Among 9 patients with s.c. nodules, the incidence of esophageal dilatation was 56% compared with 21% for 34 patients without s.c. nodules. Unexpected orderly correlations (not specified) were observed between the incidence of esophageal dilatation and grades of RA tests, stage of joint X-ray, or duration of disease. The incidence of esophageal dilatation among 6 rheumatoid patients with a negative RA test was 0% compared with incidences ranging from 22 to 33% for 37 patients with positive RA tests. The incidences of esophageal dilatation among 3 stage I disease patients, 9 stage II patients, 20 stage III patients, and 10 stage IV patients were 0, 22, 30, and 40%, resp. When the duration of the disease was less than 1 yr, the incidence of esophageal dilatation was 14% compared with 20% for disease durations of 1-5 yr and 32% for rheumatoid disease with a duration of more than 5 yr. The findings suggest the existence of "rheumatoid esophageal disease."

5567 SYMPTOMATIC DIFFUSE ESOPHAGEAL SPASM: MANOMETRIC FOLLOW-UP AND RESPONSE TO CHOLINERGIC STIMULATION AND CHOLINESTERASE INHIBITION.

(Eng.) Mellow, M. (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Gastroenterology* 73(2):236-240; 1977.

The stability of manometric findings in symptomatic diffuse esophageal spasm (SDES) over time and the response of the body of the esophagus in SDES to both a direct cholinergic agonist and a cholinesterase inhibitor were examined in five patients and eight controls. The criteria for SDES included: (1) history of spontaneous postprandial substernal chest pain, (2) dysphagia, (3) radiological diagnosis of diffuse esophageal spasm, (4) esophageal manometry in which at least 30% of responses to swallowing were abnormal, showing repetitive and/or simultaneous contractions having increased mean amplitude (>35 mm Hg) and a mean duration of over 7.5 sec, and (5) presence of some peristaltic responses. All five patients had undergone motility studies 1-13 (mean, 8) months previously; the manometric abnormalities remained unchanged at the follow-up evaluation. The mean lower esophageal sphincter pressure was unchanged (24.4-25.4 mm Hg). The mean duration of esophageal contractions in the distal esophagus was 8.5 ± 0.5, 6.2 ± 0.3, and 5.3 ± 0.3 sec in SDES, eight controls, and eight controls with heartburn, resp. The response to edrophonium chloride (100 µg/kg, i.v.) in SDES (14.4 ± 2.3 sec) was significantly greater than that in controls (3.9 ± 0.7 sec, $p<0.001$) or in controls with heartburn (2.4 ± 0.4 sec, $p<0.001$). The response to bethanechol (40 µg/kg, s.c.) in SDES (12.5 ± 4.8 sec) was significantly greater than that in controls (0.8 ± 0.4, $p<0.02$) or in patients with heartburn (0.4 ± 0.2, $p<0.01$). Chest pain occurred in six of eight patients with SDES after edrophonium and in three of six patients after bethanechol; chest pain did not occur in the other subjects. The results suggest that SDES is a relatively homogeneous entity, with respect to both maintaining stability of manometric abnormalities and response to two different pharmacological agents.

5568 TRANSHEPATIC OBLITERATION OF GASTROESOPHAGEAL VARICES: RESULTS IN ACUTE AND NONACUTE BLEEDERS. (Eng.) Viamonte, M., Jr.; Pereiras, R.; Russell, E.; Le Page, J.; Hutson, D. (Univ. Miami Sch. Medicine and Affiliated Hosp.,, P.O. Box 520875, Miami, FL 33152). *Am. J. Roentgenol.* 129(2):237-241; 1977.

Transhepatic portal vein catheterization and variceal obliteration were carried out in 73 patients with liver cirrhosis and bleeding gastroesophageal varices. Gastroesophageal varices were successfully obliterated in 32 actively bleeding patients and in 35 patients with stabilized bleeding gastroesophageal varices. The remaining six procedures were technical failures. Follow-up examinations in 10 patients from 1 month to 3 yr later showed persistent obliteration of embolized veins. Recurrence of variceal bleeding occurred in nine patients. This method should be considered as a palliative, effective adjuvant to the medical treatment of patients with bleeding gastroesophageal varices.

87 TOUCH SMEAR CYTOLOGY FOR ENDOSCOPIC DIAGNOSIS OF GASTRIC CARCINOMA. (Eng.) Tam-
a, K.; Masuzawa, M.; Akiyama, T.; Fukui, O. (Natl.
aka Hosp., Hoenzaka, Higashi-Ku, Osaka, Japan).
. *J. Gastroenterol.* 67(5):463-467; 1977.

e accuracy of histology and touch smear cytology
specimens obtained by endoscopic target biopsy
s studied retrospectively. Sixty-five cases of
all excavated-type gastric carcinoma, in-
uding 27 cases of early carcinoma, were examined.
histology alone, 89% of cases were diagnosed ac-
rately, 85% by touch smear cytology alone and
% by combined examination. By touch smear cy-
logy, 10 of 16 specimens were diagnosed as posi-
ve, although extensive necrosis prevented his-
logic study. This study demonstrates that the
oor, as well as the edge and margin, of the exca-
ted lesion is an important target site for biopsy.
uch smear cytologic techniques aid in the diag-
sis of gastric malignancy.

8 RADIOIMMUNOASSAY OF CARCINOEMBRYONIC ANTIGEN IN GASTRIC CARCINOMA. (Fre.) Dedieu,
Chatal, J. F.; Gibon, M.; Gaillard, F.; Leduc,
L.; Perrin, D.; Miniconi, P. (Clinique Medicale
pedeutique, Hopital Saint-Jacques, Hotel-Dieu,
.R., Nantes, France). *Gastroenterol. Clin. Biol.*
):415-424; 1977.

um levels of carcinoembryonic antigen (CEA) were
sured in 66 patients with gastric carcinoma,
patients with other digestive tract carcinomas,
patients with nonmalignant gastric diseases,
85 normal controls. Normal values were less
n 10 ng/ml; they were found in 38% of the pa-
nts with benign disease and in 31% of cancer
ients. Elevated values were almost always less
than 50 ng/ml in benign stomach diseases. CEA levels averaged 62 ng/ml in patients with highly differentiated carcinomas, with values greater than 50 ng/ml always being associated with lymphatic invasions and metastases. In undifferentiated carcinomas, CEA levels averaged 30 ng/ml. Normal CEA levels after gastrectomy were not necessarily indicative of complete removal of cancerous tissues, but when CEA values rose after surgery, they were always associated with incomplete resections or further metastases. CEA levels, therefore, may be valuable in the early detection of tumor recurrences.

5589 HLA ANTIGENS AND Ia ANTIBODY IN THE GASTRIC CANCER PATIENT. (Eng.) Tsuji, K.; Ito, M.; Inouye, H.; Nose, Y.; Hoshino, K.; Shibuya, K.; *et al.* (Tokai Univ. Sch. Medicine, Bohseidai, Isehara, Kanagawa 259-11, Japan). *Prog. Clin. Biol. Res.* 16:29-37; 1977.

The possible association of 18 histocompatibility antigen (HLA) specificities in HLA-A locus and 23 specificities in HLA-B locus with susceptibility to gastric cancer was investigated in 87 patients and 355 controls. Significantly decreased antigen, HLA-B5 (17.2%), was found in gastric cancer patients, compared with 40.0% in controls. χ^2 For this antigen difference is 15.8 (corrected $p<0.005$). The most frequent HLA haplotype was A9-B5 in controls and A2-Blank B locus antigen in gastric cancer patients. No reaction was found in HLA antiserum, Bou-Pri with cells of gastric cancer patients, compared with 29.4% in control subjects. No linkage was observed between HLA-A and -B locus antigens and gastric cancer in a family study with double the frequency of HLA haplotype A2-BW40. Ia-like B cell specific antibody was found in 2 of 20 gastric cancer patients in a preliminary study. There was no clear association between B cell specific antibody and clinical implications.

5590 GASTRIC LYMPHOMA, A RADIOLOGIC DIAGNOSIS.

(Eng.) Menuck, L. S. (Univ. Hosp., Univ. California at San Diego, La Jolla, CA). *Gastrointest. Radiol.* 1(2):157-161; 1976.

Thirty cases of gastric lymphoma (reticulum cell sarcoma, 14; lymphosarcoma, 11; Hodgkin's disease, 15) were compared with 50 cases of gastric carcinoma to see if there are radiologic features that are significant and easily applicable in the separation of the two entities. Gastric lymphoma presents as a much larger lesion (average size 11.9 cm) than gastric carcinoma (average size 5.6 cm). Forty percent of the gastric lymphomas and only 4% of the gastric carcinomas were over 15 cm in length. Multiple radiographic patterns are common in gastric lymphoma, being seen in 72% compared to 24% of gastric carcinomas. The most frequent primary radiographic finding in gastric lymphoma (in 56% of patients) was a circumferential, concentric infiltrating pattern consisting of enlarged bizarre rugal folds and submucosal nodularity without significant narrowing of the gastric lumen. A solitary lesion, with or without ulceration, was the most common finding in gastric carcinoma (66% of the cases). Hodgkin's disease was reported to be an exception to other lymphomas in that the presenting lesion was comparable in size and radiographic appearance to gastric carcinoma. Radiographic evaluation is still the most reliable means of diagnosing gastric lymphoma preoperatively. By use of this technique, gastric lymphoma can be distinguished from gastric carcinoma in most cases.

5591 FACTORS IN THE PROGNOSIS OF GASTRIC LYMPHOMA.

(Eng.) Lim, F. E.; Hartman, A. S.; Tan, E. G. C.; Cady, B.; Meissner, W. A. (Milford Chest Hosp., Godalming, Surrey, England). *Cancer* 39(4):1715-1720; 1977.

The tumor-nodes-metastases (TNM) staging classification for gastric carcinoma was applied to 50 consecutive cases of primary gastric lymphoma, and prognostic factors were determined. The most common locations of gastric lymphoma in these patients were the antrum, pylorus, and lesser curvature. The size of the primary tumor varied from 0.3 to 15 cm. Of 41 patients who underwent resection and survived operation, the determinate 5-yr survival rate was 59% and the determinate 10-yr survival rate was 43%. Patients with T1 lesions (confined to the mucosa) or T2 lesions (involving the mucosa, the submucosa including the muscularis propria, and extending to or into the serosa but not penetrating through the serosa) had a determinate 5-yr survival rate of 82% and 65%, resp.; whereas patients with T3 lesions (penetrating through the serosa with or without invasion of contiguous structures) had a 5-yr determinate survival rate of only 24%. Patients without perigastric nodal metastases had a determinate 5-yr survival rate of 88%, while patients with N1 lesions (metastasis to the perigastric lymph nodes in the immediate vicinity of the primary tumor) had a determinate 5-yr survival rate of 32%. Overall, patients with primary gastric lymphoma appear to have a much better prognosis for survival than patients with gastric carcinoma since the latter present with far more frequent serosal penetration and nodal and distant metastases. Survival statistics obtained for each stage category in patients with primary gastric lymphoma were remarkably similar to survival statistics for each respective stage in gastric carcinoma patients.

5592 GASTRIC GLAND METAPLASIA IN THE SMALL AND LARGE INTESTINE.

(Eng.) Yokoyama, I.; Kozuka, S.; Ito, K.; Kubota, K.; Yokoyama, Y.; Kondo, T. (Nagoya Univ. Sch. Medicine, 65 Tsurumacho Showaku, Nagoya, 466, Japan). *Gut* 18(3):214-218; 1977.

Fifty-six surgical specimens with various ulcerative intestinal disorders were investigated histologicall for evidence of gastric gland metaplasia. Thirty-one specimens showed pyloric gland metaplasia. Among the 31 patients with pyloric gland metaplasia, 5 showed true gastric metaplasia, consisting of parietal cells, chief cells, and mucous neck cells. The percentage of true gastric metaplasia among pyloric gland metaplasia was as high as 16% with an overall frequency of 9% among various ulcerative intestinal disorders. The mechanism of pyloric gland metaplasia and true gastric metaplasia may occur secondarily to the submucosal response to ulcer healing and subsequent alteration of the intraluminal condition in the intestine.

5593 MEAT-STIMULATED GASTRIN RELEASE AND ACID SECRETION IN PATIENTS WITH PYLORIC STENOSIS.

(Eng.) Tani, M.; Shimazu, H. (Faculty Medicine, Univ. Tokyo, 7-3-1 Hongo, Bunkyo-Ku, Tokyo, Japan). *Gastroenterology* 73(2):207-210; 1977.

Different mechanisms of meat-stimulated acid secretion were studied in 5 patients with pyloric stenosis, 20 patients with inactive and 12 with active duodenal ulcer (DU), and in 10 healthy controls. Gastric acid secretion and gastrin levels were measured after instillation of tetragastrin or meat extract into the stomach of patients and controls. Basal gastric acid secretion and basal gastrin levels were also determined. Acid secretio in response to meat extract increased significantly above basal level and amounted to 50.2% of maximal tetragastrin response in healthy volunteers, 44.2% in the inactive DU group, 60.6% in the active DU group, and 82.4% in the pyloric stenosis group. In the inactive DU group the acid secretion in respons to meat extract was similar to that in healthy volu teers. In the active DU group, acid secretion in r sponse to meat extract was significantly higher tha in healthy volunteers (16.70 ± 1.93 mEq/hr versus 8.37 ± 1.62 mEq/hr, $p<0.005$) or in the inactive gro (10.24 ± 1.47 mEq/hr). However, integrated gastrin response to meat extract in the active DU group was similar to the levels in the inactive DU group or the healthy volunteers. In contrast, integrated gastrin response, acid response to meat extract, and maximal response to tetragastrin in the pyloric stenosis group showed the highest levels. Thus, the increased amount of gastric phase of acid secretion in the pyloric stenosis group is explained through a combination of release of an increased amount of gastrin and increased responsiveness of oxyntic cells. The increase in the inactive DU group is explained through increased responsiveness of oxyntic cells rather than through release of an increased amount of gastrin.

5594 RUPTURE OF THE STOMACH FOLLOWING OXYGEN INSUFFLATION INTO THE STOMACH. EXPERIMENTAL AND CLINICAL STUDY.

(Ger.) Geroulanos, S.; Hahnloser, P.; Senning, A. (Chirurgische Universitatsklinik A, Kantonsspital, CH-8091 Zurich, Switzerland). *Helv. Chir. Acta* 43(5/6):803-807; 1976.

Four cases of stomach rupture following oxygen insufflation and the effect of stomach expansion on circulation, acid-base balance, and blood gases in dogs are described. One 60-yr-old woman who was given O_2 (4 l/min via a nasal catheter) for cardiac decompensation because dyspneic and cyanotic, went into shock, and died 2 hr later. At autopsy, an odorless gas escaped from the abdomen and two parallel mucosal ruptures 3 and 8 cm long were discovered in the stomach wall, with the longest rupture protruding into the stomach lumen. An oxygen tube (O_2, 4 l/min) was mistakenly connected to a stomach tube in a 32-yr-old patient given a cardiac valve prosthesis. The patient developed shortness of breath and upper gastric pain with swollen abdomen and went into shock. The error was discovered 5 min later; x-ray examination of the abdomen showed a massive pneumoperitoneum, and the peritoneal cavity was punctured. A laparotomy revealed a 12-cm-long seromuscular tear, which was repaired. Similar accidents occurred in a 34-yr-old man submitted to a stomach resection of duodenal ulcer and a 60-yr-old woman given a mastectomy for breast cancer who were inadvertently given O_2(4-6 l/min) into a stomach tube. Both patients recovered successfully. Experiments in pentobarbital-anesthetized dogs showed that stomach rupture occurred at pressures between 67 and 360 mm Hg; cardiac output decreased by 50% and oxygen saturation by 45% at a pressure of 80 cm H_2O. Increasing acidosis was noted; dangerous values were reached 1-2 min after pressure release.

5595 CIMETIDINE IN PATIENTS WITH GASTRIC ULCER: A MULTICENTRE CONTROLLED TRIAL.

(Eng.) Frost, F.; Rahbek, I.; Rune, S. J.; Jensen, K. B.; Gudmand-Hoyer, E.; Krag, E.; *et al.* (Glostrup Univ. Hosp., Glostrup, Denmark). *Br. Med. J.* 2(6090): 795-797; 1977.

The therapeutic efficacy of p.o. cimetidine (1 g/day) was compared with that of placebo in a double-blind trial of 45 adult outpatients with endoscopically confirmed gastric ulceration. After 6 weeks, 18 of the 23 patients receiving cimetidine showed complete ulcer healing, compared with only 6 of the 22 patients receiving placebo. The cimetidine group also had fewer days with pain than the placebo group, but the difference was not statistically significant. Cimetidine seems to promote healing of gastric ulcers without severe side-effects, although its effect on pain is less pronounced in patients with gastric ulcers than in patients with duodenal ulcers.

5596 PERSONALITY PATTERN OF PATIENTS WITH CHRONIC GASTRIC ULCER: STUDY OF NEUROTICISM AND EXTROVERSION IN A GASTRIC ULCER AND A CONTROL POPULATION.

(Eng.) Piper, D. W.; Greig, M.; Thomas, J.; Shinners, J. (Royal North Shore Hosp., St. Leonards, New South Wales 2065, Australia). *Gastroenterology* 73(3):444-446; 1977.

The personality patterns of 44 patients with chronic gastric ulcer were compared with a control group matched for age, sex, and place of residence. The personality pattern was studied by the Eysenck Personality Inventory, and personality was assessed in terms of neuroticism and extroversion. The relevance of social class was also studied. The gastric ulcer patients did not differ from the control group, except among the male population in which the gastric ulcer population was significantly more neurotic and less extroverted than their controls; the neuroticism score in the gastric ulcer patients was 10.73 ± 1.48, while that in controls was 6.87 ± 1.42 ($0.02>p>0.01$), and the extroversion score in ulcer patients was 7.87 ± 0.88, while that in the controls was 10.67 ± 1.71 ($0.01>p>0.001$).

5597 TOTAL GASTRECTOMY WITH SUBSTITUTE STOMACH.

(Ger.) Nadjafi, A. S. (Chirurgische Klinik, Stadtisches Krankenhaus, D-7990 Friedrichshafen/Bodensee, W. Germany). *Helv. Chir. Acta* 44(1/2):187-191; 1977.

A modified technique of jejunum reservoir construction after total gastrectomy or subtotal stomach resection for gastric cancer is described. The first jejunal loop is cut transversely (minimal skeletization of the mesenterium, only two vascular ligatures). The distal jejunal loop is pulled toward the rectocolon and an end-to-end anastomosis with the duodenum and a side-to-end anastomosis with the esophagus are done, followed by a long enteroanastomosis between both jejunal loops where the descending crus is again cut. The proximal end is included in the enteroanastomosis; the free end is pulled down toward the rectocolon and anastomosed end-to-end with the first jejunal loop. In order to maintain the esophagojejunal anastomosis and prevent reflux, the lateral walls of the reservoir crus are pulled up and affixed to the esophagus like a collar. Five such procedures were performed without postoperative complications and 2 months after surgery the reservoir has already approached the normal emptying time.

5598 EFFECT OF DIETARY FIBER ON COMPLICATIONS OF GASTRIC SURGERY: PREVENTION OF POSTPRANDIAL HYPOGLYCEMIA BY PECTIN. (Eng.) Jenkins, D. J. A.; Gassull, M. A.; Leeds, A. R.; Metz, G.; Dilawari, J. B.; Slavin, B.; *et al.* (Central Middlesex Hosp., Park Royal, London NW10 7NS, England). *Gastroenterology* 73(2):215-217; 1977.

The effect of pectin on blood glucose levels, breath H_2 (as an index of carbohydrate fermentation), and symptoms was investigated in nine postgastric surgery patients with hypoglycemia. Two hours after taking 50 g of glucose, the blood glucose levels in each patient had fallen below 50 mg/100 ml. The addition of 14.5 g of pectin to a 50-g p.o. glucose load prevented the occurrence of hypoglycemic symptoms and maintained the blood glucose levels above control values by 64% at 90 min ($p<0.002$) and 46% at 120 min ($p<0.01$). Breath H_2 production was abolished or reduced by pectin in all five cases in which this had previously occurred. A trial of 10 g of pectin daily has prevented severe recurrent postprandial hypoglycemic attacks for 5 weeks in the one patient in whom this was tried. Pectin and other unabsorbable polysaccharides are likely to prove useful in the treatment of abnormal carbohydrate absorption after gastric surgery.

5599 GASTRIC ULCER AFTER THE NISSEN FUNDOPLICATION: A COMPLICATION OF ALKALINE REFLUX. (Eng.) Bremner, C. G. (Dept. Surgery, Univ. Witwatersrand, Johannesburg, South Africa). *S. Afr. Med. J.* 51(22):791-793; 1977.

5600 EPIDEMIOLOGY OF GASTRIC AND COLO-RECTAL CANCER IN THE UNITED STATES AND CHILE WITH PARTICULAR REFERENCE TO THE ROLE OF DIETARY AND NUTRITIONAL VARIABLES, NITRATE FERTILIZER POLLUTION, AND N-NITROSO COMPOUNDS. (Eng.) Zaldivar, R. (2170 N.W. 11th St., Suite 53, Miami, FL 33125). *Zentralbl. Bakteriol.* [*Orig. B*] 164(3):193-217; 1977.

3 EFFECT OF ATROPINE ON FOOD-STIMULATED
GASTRIN RELEASE AFTER TRUNCAL VAGOTOMY IN
. (Eng.) Hansky, J.; King, R. W. F. (Prince
ry's Hosp., Melbourne, Australia 3004). *Gas-*
enterology 73(2):205-206; 1977.

determine whether vagal integrity is necessary
the enhancement of gastrin release by atropine,
dies were carried out in 10 men 2-17 months
er truncal vagotomy. Atropine (1.2 mg, i.m.)
no effect on the basal level of serum immuno-
ctive gastrin, but it caused a significant in-
ase in both the peak postprandial gastrin (135-
pg/ml without atropine, 139-308 pg/ml with atropine) and the integrated gastrin response (10.2 and 15.5 ng/min/ml for 2 hr, resp., $p<0.05$). This indicates that vagal integrity is not essential for the enhancement of the gastrin response by atropine and implies a direct effect by atropine on the antral gastrin cell.

5624 EFFECT OF ATROPINE AND PROXIMAL GASTRIC VAGOTOMY ON THE ACID RESPONSE TO FUNDIC DISTENSION IN MAN. (Eng.) Grotzinger, U.; Bergegardh, S.; Olbe, L. (Sahlgren's Hosp., Goteborg, Sweden). *Gut* 18(4):303-310; 1977.

The mechanisms by which distention of the oxyntic gland area elicits gastric acid secretion were studied in 4 healthy men and 12 men with duodenal ulcer (DU). Graded balloon distention of the gastric fundus and body caused increments in acid output related to the distention volumes in all subjects. The mean peak distention response amounted to about 50% of the mean peak acid output (PAO_{pg}) evoked by i.v. infusion of pentagastrin (300 μg/hr), eliciting maximum observed secretory response. During distention with the largest balloon volume, 1.0 mg of atropine injected i.v. significantly depressed the acid secretory rate, the median inhibition amounting to about 80%. In two patients with DU, 2-5 mg of atropine completely abolished acid secretion during fundic distention. In nine subjects with DU, complete proximal gastric vagotomy profoundly depressed the secretory responses to graded fundic distention, eliminating the acid response to the smallest balloon volume used. A slight, but significant, response to the largest distention volume persisted after complete vagotomy. Incomplete proximal gastric vagotomy in five patients reduced the distention responses only moderately, and the peak acid response to fundic distention as related to PAO_{pg} remained unchanged. Distention of the gastric fundus and body in man stimulates acid secretion by an atropine-sensitive, presumably cholinergic, reflex mechanism. The findings after vagotomy are in agreement with the concept that this reflex mechanism is conveyed by both short intramural and long vagovagal pathways.

5625 CONTROLLED TRIALS OF ALUMINUM HYDROXIDE GELS FOR PEPTIC ULCER.

(Eng.) Littman, A.; Welch, R.; Fruin, R. C.; Aronson, A. R. (Veterans Admin. Hosp., Hines, IL 60141). *Gastroenterology* 73(1):6-10; 1977.

Experiments conducted over a 14-yr period to determine whether aluminum hydroxide gel (AG) is effective in relieving peptic ulcer pain are described. In 44 individual pain episodes, complete relief was obtained by 15-ml doses of AG in 79% and by an indistinguishable dummy gel (DG) in 45% ($p<0.05$). In 48 identical blind trials replicated at another hospital, the difference was not significant. The gels were also tested against ulcer pain induced by intragastric acid instillation (Palmer test) in 35 patients; pain was relieved by AG in 63% and by DG in 62%. Presumed effectiveness in terminating ulcer episodes was studied in 65 patients admitted for pain; 37 received milk and cream hourly, and 28 did not. All were treated with 15 ml of AG or DG during waking hours. Median time for complete disappearance of spontaneous pain was 3 days for AG and 7 days for DG, the same in both groups. The acid instillation test was repeated every few days in all patients. For the milk and cream group it became negative after 4 days with AG and after 6 days with DG. In 18 patients with gastric ulcer treated for 4 weeks, AG led to greater reductions in size than did DG. A number of these trials indicate AG to be more effective than DG, but sampling and other methodological problems limit the certainty of any conclusions.

5626 EFFECTIVE CIMETIDINE THERAPY OF DUODENAL ULCER: RESULTS OF DOUBLE BLIND STUDY.

(Ger.) Domschke, W.; Domschke, S.; Lux, G.; Belohlavek, D.; Neidhardt, B.; Demling, L. (Medizinische Klinik mit Poliklinik, Universitat Erlangen-Nurnberg, Krankenhausstr. 12, 8520 Erlange W. Germany). *Dtsch. Med. Wochenschr.* 101(48):1752-1755; 1976.

Effectiveness of treatment of 12 male duodenal ulce patients with the histamine H_2-receptor antagonist cimetidine (4 x 200 mg/day, p.o.) was demonstrated in comparison to treatment with a placebo (lactose capsules) in a double-blind study. Half-time of ulcer healing was approximately 6 days for cimetidine and 20 days for the placebo. Healing was significantly more rapid in cimetidine-treated patients than in those on placebo ($p< 0.0005$). Four week cimetidine therapy did not produce any changes in gastric secretion of acid, protein, pepsin, and *N*-acetylneuraminic acid-containing glycoproteins or in bicarbonate and enzyme production and in clinical-chemical parameters.

5627 POST-VAGOTOMY INSULIN TEST: IMPROVED PREDICTABILITY OF ULCER RECURRENCE AFTER CORRECTIONS FOR HEIGHT AND COLLECTION ERRORS.

(Eng.) Maybury, N. K.; Faber, R. G.; Hobsley, M. (Middlesex Hosp. and Medical Sch., London, England). *Gut* 18(6):449-456; 1977.

To investigate the influence of sex and height in duodenal ulcer, insulin-stimulated gastric secretion was studied in 20 women and 54 men with unoperated duodenal ulcer (DUs). Three indices of secretion were studied: observed volume, acid outpu and volume of gastric juice corrected for pyloric loss and duodenal reflux (Vg). These three measurements were expressed both as peak secretion and as secretion during the 0.5- to 2.0-hr period after i sulin administration and also both before and afte standardization for height, making 12 different in ces in all. A significant correlation between insulin-stimulated secretion and height in DUs was fou A method of standardizing each patient's secretion for height is described. There was a significantl higher insulin-stimulated secretion in men than in women, and this difference could be explained by their difference in height. For each of the 12 indices of secretion, the range of secretion for the unoperated subjects was obtained. The same indices were measured in 155 postvagotomy patients including 33 patients with recurrent DUs, and compared with the ranges of secretion established in the unoperated patients. Responses above the lowe 95% tolerance limit of the preoperative range were designated positive and those below negative. The Hollander status was determined. It was found tha the least satisfactory criterion was Hollander's (7% false-negative and 69% false-positive). The best was 0.5-2 Vg standardized for height (3% fals negatives and 43% false positives). The improvement in predictability was significant at the 0.0005 level.

SMALL INTESTINE

5648 THE EFFECT OF PELVIC IRRADIATION ON ILEAL FUNCTION. (Eng.) Stryker, J. A.; Hepner, G. W.; Mortel, R. (Milton S. Hershey Medical Center, Hershey, PA 17033). *Radiology* 124(1):213-220; 1977.

The role of ileal dysfunction as a factor in the etiology of radiation-induced diarrhea was studied in 33 patients using the $[1\text{-}^{14}C]$cholyl glycine breath test. All patients (aged 44-78 yr) were undergoing radiotherapy to the pelvis for gynecological neoplasms. Breath tests were performed in the 1st and 5th weeks of treatment and 19 patients had a third test 3 months after treatment. In the first test, 29.9 ± 16.8% of the administered dose was excreted in breath ^{14}C in 24 hr. This rose to 47.3 ± 15.9% ($t=6.08$, $p<0.001$) in the 5th week and fell to 36.3 ± 16% ($t=2.29$, $p<0.05$) at 3 months. Eight patients had breath tests performed 1 yr post-treatment, and the test percentages were 32.7 ± 7.8% ($t=1.19$, $p>0.10$). The increase in $^{14}Co_2$ excretion in the 5th week of treatment occurred at a time when most patients were having diarrhea. The data suggest that bile acid malabsorption due to ileal dysfunction may be a factor in radiation-induced diarrhea, which occurs in nearly all patients during pelvic irradiation.

5649 APPLICATION OF A STABLE ISOTOPE (^{13}C)-LABELED GLYCOCHOLATE BREATH TEST TO DIAGNOSIS OF BACTERIAL OVERGROWTH AND ILEAL DYSFUNCTION. (Eng.) Solomons, N. W.; Schoeller, D. A.; Wagonfeld, J. B.; Ott, D.; Rosenberg, I. H.; Klein, P. D. (Pritzker Sch. Medicine, Chicago, IL). *J. Lab. Clin. Med.* 90(3):431-439; 1977.

Stable isotope labeling and mass spectrometric analysis were applied to the development of a glycocholate (GC) deconjugation breath test using ^{13}C as the isotopic marker. In 13 adults with a wide range of conditions associated with upper intestinal bacterial overgrowth or ileal dysfunction, the intraluminal deconjugation of standard glycocholate-1-^{14}C-glycine was compared to that of simultaneously administered glycocholate-1-^{13}C-glycine or glycocholat 1,2-^{13}C-glycine. The correlations of net deconjugation as measured by the radioactive isotope- and stable isotope-labeled bile salt were excellent (correlation coefficient=0.952). Exogenous bile salts did not affect the reproducibility of the breath test. There was statistical identity between the results of tests using glycocholate-1-^{13}C-glycin or glycocholate-1,2-^{13}C-glycine. The calculated detection limits employing a dose of 7.5 mg/kg body weight of glycocholate-1,2-^{13}C-glycine were 4.7% and 6.2% at the 95% and 99% confidence levels, resp. This test offers potential advantages of safety and acceptability for infants, children, pregnant women, and women at risk of pregnancy.

5650 INTESTINAL BYPASS ARTHRITIS: ASSOCIATION WITH CIRCULATING IMMUNE COMPLEXES AND HLA B27. (Eng.) Rose, E.; Espinoza, L. R.; Osterland, C. K. (Royal Victoria Hosp., Montreal, Quebec H3A 1A1, Canada). *J. Rheumatol.* 4(2):129-134; 1977.

The cases of two patients in whom arthritis following intestinal bypass surgery for obesity was associated with the presence of circulating immune complexes (CIC) and histocompatibility antigen (HLA) B27 are described. The arthritis was characteristically intermittent and controlled by low dose prednisone, indomethacin, and tetracycline therapy. The findings suggest that immune complexes play a role in the pathogenesis of arthritis associated with this condition, and that the association with HLA B27 may predispose to the development of this complication.

5651 PNEUMATOSIS CYSTOIDES INTESTINALIS FOLLOWING INTESTINAL BYPASS. (Eng.) Ikard, R. W. (Suite 600, Doctor's Pavilion, 1916 Patterson St. Nashville, TN 37203). *Am. Surg.* 43(7):467-470; 1977

Two cases of pneumatosis cystoides intestinalis occurring in the bypassed small bowel following intestinal bypass for treatment of obesity are presented. The first patient, a 36-yr-old woman, underwent an end-to-end jejunoileostomy, using 10 inches of proximal jejunum and 8 inches of distal ileum. The patient tolerated the procedure poorly, experiencing diarrhea, intermittent hypokalemia, nausea, weakness, and anorexia. Normal bowel continuity was restored, and, at this laparotomy, the distal one-third of the defunctionalized small bowel was found to be coated with thin cysts measuring 1-3 cm in diameter. The cysts were entirely in the subserosal plane. The ileosigmoid colostomy was markedly dilated, and there were feces in the distal part of the bypassed ileum. The second patient, a 36-yr-old woman, tolerated a similar procedure well, and the initial postoperative course was uncomplicated. She died of acute myocardial infarction 10 months later, and autopsy revealed numerous gas-containing cysts in all layers of the bowel, although most prominently in the subserosal plane. In addition, the mesenteric attachments, adjacent connective tissues, and regional lymph nodes were involved. Microscopic examination revealed the cysts to be lined by numerous giant cells with a granulomatous and fibrous reaction in the stroma around the cysts. Stain and culture of the cysts for bacteria, fungi, and *Mycobacterium tuberculosis* were negative. The etiology of these lesions is unknown, but is probably related to fecal reflux into defunctionalized bowel with the attendant alteration of bacterial flora.

5652 STUDIES OF IDIOPATHIC INTESTINAL PSEUDO-OBSTRUCTION. I. HEREDITARY HOLLOW VISCERAL MYOPATHY: CLINICAL AND PATHOLOGICAL STUDIES. (Eng.) Schuffler, M. D.; Lowe, M. C.; Bill, A. H. (United States Public Health Service Hosp., P.O. Box 3145, Seattle, WA 98114). *Gastroenterology* 73(2):327-338; 1977.

The case of a 15-yr-old girl with idiopathic intestinal pseudo-obstruction is reported. She presented with a long-term history of low grade obstructive symptoms, diarrhea, and poor nutrition culminating in an acute obstructive attack leading to exploratory laparotomy. At surgery, the small bowel and colon were dilated, with no mechanical obstruction found. Further evaluation revealed a diffuse disorder of gastrointestinal smooth muscle function involving esophagus, small bowel, and colon. Because medical management failed to control symptoms, a gastrojejunostomy was carried out to bypass a megaduodenum. A third laparotomy was necessary 2 months later because of intractable obstructive symptoms. At this last laparotomy, the afferent loop was taken down, and a duodenoplasty and duodenojejunostomy were performed, resulting in clinical improvement. Light and electron microscopy of the excised small intestine showed marked thinning and degeneration of the smooth muscle, with replacement by fibrous tissue. Marked vacuolization was present. The myenteric plexus was normal. This case demonstrates that a degenerative disease of smooth muscle may be one cause of idiopathic intestinal pseudo-obstruction.

5653 ENDOMETRIOSIS OF THE SMALL INTESTINE. REPORT OF FOUR NEW CASES OF STENOSIS OF THE SMALL INTESTINE. (Fre.) Leborgne, J.; Arzul, C.; Le Neel, J. C.; Visset, J. (Clinique Chirurgicale A, place Alexis-Ricordeau, 44035 Nantes, France). *J. Chir. (Paris)* 113(2):143-151; 1977.

Four new cases of stenosis of the ileum caused by intestinal endometriosis in women aged 45-52 yr are reported. This rare complication is very difficult to diagnose, since 50% of cases are without associated genitopelvic symptoms. However, the condition must be considered when an isolated ileal tumor is accompanied by the catamenial recurrence of digestive problems. Surgical intervention is almost always necessary to confirm the diagnosis. Since the intestinal mucosa remains intact, the condition is easily differentiated from a malignant process, and a limited resection is indicated. Hormone therapy should be routinely instituted postoperatively.

5654 GARDNER'S SYNDROME AND DUODENAL ADENOCARCINOMA. (Fre.) Suzanne, J.; Camelot, G.; Miguet, J. P.; Carbillet, J. P.; Gillet, M.; Carayon, P.; Gisselbrecht, H. (Service d'Hepato-gastroenterologie, Centre Hospitalier et Universitaire, place Saint-Jacques, F-25030 Besancon, France). *Gastroenterol. Clin. Biol.* 1(5):455-460; 1977.

A case of adenocarcinoma of the ampulla of Vater is reported in a 46-yr-old man with Gardner's syndrome. This rare type of cancer is almost always associated with duodenal polyps, which are found in 10% of cases of familial multiple polyposis. Since the risk of malignant degeneration of duodenal polyps is extremely high in patients with Gardner's syndrome, a preventative duodenopancreatectomy may be advisable. If the duodenal polyps are few or isolated, a polypectomy and/or endoscopic surveillance may be indicated.

5655 IMMUNOBLASTIC SARCOMA (RETICULUM-CELL SARCOMA) OF THE GASTRO-INTESTINAL TRACT IN A CASE OF DERMATITIS HERPETIFORMIS DUHRING. (Ger.) Gebbers, J. O.; Otto, H. F.; Muller-Weiland, K. (Pathologisches Institut der Universitat, Martinistr. 52, 2000 Hamburg 20, W. Germany). *Dtsch. Med. Wochenschr.* 102(7):242-247; 1977.

A 43-yr-old man with a 20-yr history of dermatitis herpetiformis had a concurrent reticulum cell sarcoma of the upper jejunum and abdominal lymph nodes for the past 4 yr. Initially, the patient complained of abdominal pain, weight loss, and diarrhea. A partial Billroth II stomach resection was done at which time callous changes of the proximal jejunum were found along with a red, edematous, rigid wall. The small intestinal mucosa showed no folds and was covered with white spots, and the mesenteric lymph nodes were enlarged. At this time a pyloric ulcer and Crohn's disease of the small intestine were diagnosed, and pathological findings revealed nonspecific gastroduodenitis or jejunitis. The patient continued to lose weight and was readmitted with acute intestinal bleeding followed by vomiting, diarrhea, and tarry stools. Roentgenological tests showed marked swelling and irregular folds in the loop of the small intestine. Several biopsies revealed partial to subtotal villous atrophy with crypt hyperplasia. Three esophagogastrojejunoscopies showed the absence of the Kerckring's fold with rigid, edematous mucosa and isolated ulcers. The patient died shortly thereafter in a state of high-grade cachexia and in protracted cardiocirculatory failure. Autopsy revealed an immunoblastic sarcoma of the gastrointestinal tract with involvement of all mesenteric, portal, and parapancreatic lymph nodes and with segmental stenosing infiltration of proximal segments of the jejunum. Histologically, a diffuse tumor infiltration with superficial mucosal ulceration was noted in the area of the proximal jejunum. The tumor consisted of large, round, or oval anisomorphic cells with basophilic cytoplasm.

5656 SMALL BOWEL ISCHAEMIA AND INFARCTION IN YOUNG WOMEN TAKING ORAL CONTRACEPTIVES AND PROGESTATIONAL AGENTS.

(Eng.) Hoyle, M.; Kennedy, A.; Prior, A. L.; Thomas, G. E. (Harry Hines Medical Bldg., 6161 Harry Hines Blvd., Dallas, TX). *Br. J. Surg.* 64(8):533-537; 1977.

The cases of three patients with small bowel infarction associated with oral contraceptives and progestational agents are presented. The patients ranged in age from 24-42 yr and had been taking oral contraceptives for 18 months to 3.5 yr. All patients were heavy smokers and all were of blood group A. Two patients were obese, and one of these was hypertensive. Two patients showed an increased production of fibrinogen degradation products postoperatively, requiring heparin to lower these and to prevent further necrosis. Two infarctions were due to superior mesenteric artery thrombosis and one to superior mesenteric vein thrombosis. Smoking, blood group A, and the presence of hypertension, in addition to oral contraceptives, may have contributed to small bowel infarction in these patients.

5657 RECURRENT ULCERATIVE JEJUNOILEITIS. OPERATIVE AND ENDOSCOPIC STUDY OF A NEW CASE.

(Fre.) Gouffier, E.; Phan, A.; Paraf, A.; Boddaert, A.; Chevrel, J. P. (Service de Medecine Interne et de Gastroenterologie, Hopital Franco-Musulman, F-93009 Bobigny, France). *Gastroenterol. Clin. Biol.* 1(6/7):545-552; 1977.

The case of a 35-yr-old woman with recurrent ulcerative jejunoileitis (RUJ) of 20 yr duration is described. Her attacks were characterized by fever, acute abdominal pain, and diarrhea and were separated by long symptomless intervals. An exploratory laparotomy and preoperative endoscopy showed multiple, nonspecific jejunal ulcerations separated by areas of normal or partly atrophied mucosa. RUJ may be differentiated from celiac disease by the absence of complete atrophy of the jejunal mucosa and by the ineffectiveness of a gluten-free diet and of corticosteroids. The evolution of RUJ is extremely variable, and the prognosis is usually very poor; 14/25 cases mentioned in the literature terminated fatally. Death in this case was caused by occlusions, perforations, hemorrhages, and infections; no fatal malabsorption syndrome was recorded.

5658 'ENTERAL' HYPEROXALURIA: EFFECT OF CHOLESTYRAMINE, CALCIUM, NEOMYCIN, AND BILE ACIDS ON INTESTINAL OXALATE ABSORPTION IN MAN.

(Eng.) Caspary, W. F.; Tonissen, J.; Lankisch, P. G. (Medizinischen Universitats Klinik, Humboldtalle 1, 3400 Gottingen, W. Germany). *Acta Hepatogastroenterol.* 24(3):193-200; 1977.

The effect of the oral administration of cholestyramine, neomycin, calcium, and bile acids on intestinal ^{14}C-oxalate absorption and urinary oxalate excretion was assessed in patients with normal or increased urinary oxalate excretion. Cholestyramine (8 or 16 g), neomycin (4.5 g), and acute administration of chenodeoxycholic acid (2.75 g/24 hr) did not affect significantly ^{14}C-oxalate absorption or urinary oxalate excretion. Oral administration of calcium (1.5 g) reduced ^{14}C-oxalate absorption by 88.2% and urinary oxalate excretion by 46%. Calcium-induced reduction of intestinal oxalate absorption was more pronounced in patients with hyperabsorption of oxalate than in subjects with normal oxalate absorption or excretion. Patients being treated with high doses of chenodeoxycholic acid (1.5-2.0 g/day) for dissolution of cholesterol gallstones had increased oxalate absorption and excretion; patients on long-term treatment with lower doses of chenodeoxycholic acid (0.75-1.0 g/day) exhibited normal absorption or urinary excretion of oxalate. The results suggest that calcium and bile acids play an important role in the pathogenesis of "enteric" hyperoxaluria. The beneficial therapeutic effect of cholestyramine in hyperoxaluria du to ileal resection may be caused by its bile acid binding property rather than by direct binding of oxalate within the intestinal lumen.

5659 DUODENAL INTUSSUSCEPTION SECONDARY TO BRUNNER'S GLAND HAMARTOMA: A CASE REPORT

Rieth, K. G.; Abbott, G. F.; Gray, G. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *Gastrointest. Radiol.* 2 (1):13-16; 1977.

Malabsorption

5699 RELATIVE ENTEROTOXIGENICITY OF COLIFORM BACTERIA. (Eng.) Klipstein, F. A.; Engert, R. F.; Short, H. B. (Univ. Rochester Medical Center, 601 Elmwood Ave., Rochester, NY 14642). *J. Infect. Dis.* 136(2):205-215; 1977.

The enterotoxigenicity of 12 strains of coliform bacteria (*Enterobacter cloacae, Klebsiella pneumoniae,* and *Escherichia coli*) isolated from the gastrointestinal (GI) tract of persons with either acute diarrhea or tropical sprue was determined; the enterotoxigenicity of 13 strains of the same species isolated from urine (GU) cultures from other subjects was also studied. Fractions of heat-labile (LT) and heat-stable (ST) toxins of each strain were separated by ultrafiltration, and the effect of graded concentrations of these fractions (100 μg-10 pg/ml) on water transport was assessed by *in vivo* perfusion in the rat jejunum. Enterotoxigenic activity was defined as inducement of net secretion of water. All 12 GI strains and 6 of 13 GU strains elaborated enterotoxins, but there was a million-fold quantitative difference in the potency of the toxins produced. All GI strains produced one or both forms of toxin, which had a minimal effective concentration of as low as 0.1-10 ng/ml, whereas the GU strains produced toxins of weak or, rarely, of intermediate potency. The million-fold variation in potencies of toxins elaborated by strains of Enterobacteriaceae isolated from different sources does not appear to be related either to variations in the potency of different batch preparations or to inconsistencies in the assay system itself.

5700 MUCOSAL ENTEROKINASE ACTIVITY IN PANCREATIC INSUFFICIENCY AND CELIAC DISEASE. (Eng.) Morin, C. L.; van Caillie, M.; Roy, C. C.; Lasalle, R. (Sainte Justine Hosp., 3175 St. Catherine Rd., Montreal H3T 1C5, Quebec, Canada). *Pediatrics* 60(1): 114-116; 1977.

Jejunal biopsy specimens obtained from 13 children with cystic fibrosis (CF), 13 with untreated celiac disease (CD), 3 with congenital exocrine pancreatic hypoplasia (CEPH), and 10 controls were examined histologically, and homogenates were used for the measurement of enterokinase and sucrase activities. The histologic appearance of the mucosa was normal in all patients except those with CD. Sucrase activity was significantly reduced ($p<0.05$) in children with CD (3.3 ± 1.1 U/g mucosa) as compared with those with CF (10.9 ± 1.4 U/g), CEPH (9.6 ± 0.8 U/g), and controls (10.5 ± 0.7 U/g). Enterokinase activity in children with pancreatic insufficiency (7.4 ± 0.8 U/g mucosal protein in CF and 9.9 ± 0.8 in CEPH) was higher ($p<0.05$) than that of control subjects (4.4 ± 0.2 U/g). Patients with CD had a slightly increased mean value at 5.4 U, but this was not significant. It appears that pancreatic enzymes play a large role in the turnover of enzymes in the brush border membrane and that the observed increase of mucosal enterokinase activity is probably explained by a reduced degradation in patients with exocrine pancreatic deficiency.

5701 MORE EVIDENCE FOR THE RECESSIVE INHERITANCE OF SELECTIVE ADULT TYPE LACTOSE MALABSORPTION. (Eng.) Sahi, T.; Launiala, K. (Dept. Public Health Science, Univ. Helsinki, Haartmaninkatu 3, 00290 Helsinki 29, Finland). *Gastroenterology* 73(2): 231-232; 1977.

The transition from the state of lactose absorption to that of lactose malabsorption was documented in two boys who were at risk of selective adult-type lactose malabsorption (SLM) because the parents of both boys had the disorder. The two boys were among the 16 children of four families in which both parents had SLM; 12 of the children already had symptoms of lactose malabsorption. At the ages of 14 and 9 yr, resp., the boys had normal lactose absorption. The boys were examined 3 yr and 7 months and 4 yr and 5 months later, resp., and both were shown to have lactose malabsorption; the criteria included a maximum rise in blood glucose concentration of less than 20 mg/100 ml and a maximum rise in blood galactose concentration of 5 mg/100 ml or less. One boy had not recognized milk intolerance, although he drank four to five glasses of milk/day. The period of documented transition averaged less than 4 yr. These manifestations clearly strengthen the hypothesis that SLM is a genetically determined disorder, the mode of inheritance indicating a single autosomal recessive gene.

5702 LACTOSE MALABSORPTION AND BONE MINERAL CONTENT. (Eng.) Alhava, E. M.; Jussila, J.; Karjalaninen, P.; Vuojolahti, P. (Univ. Central Hosp. Kuopio, Kuopio, Finland). *Acta Med. Scand.* 201(4):281-283; 1977.

Bone mineral density was measured by ^{241}Am gamma ray attenuation in 34 patients with lactose malabsorption and 34 controls with normal lactose absorption to determine whether lactose malabsorption leads to osteoporosis. The values in these subjects were compared with previously established normal values. The mineral densities of the distal radius did not differ significantly from normal in either the patients with malabsorption or those with normal absorption. At the cortical radius and ulna there were some statistically significant differences, both the patients with lactose malabsorption and the controls apparently having more mineral than the previously established normal values. The mean serum calcium, phosphorus, alkaline phosphatase, and total protein concentrations of the patients with malabsorption and controls did not differ significantly. Seventy percent of the patients with lactose malabsorption did not drink milk. Only two consumed more than one glass of milk per day. The average milk consumption of the controls was two glasses per day. Although lactose malabsorption leads to reduced milk consumption and calcium intake, it does not cause osteoporosis.

5703 INTESTINAL OXALATE ABSORPTION. I. ABSORPTION IN VITRO. (Eng.) Caspary, W. F. (Dept. Medicine, Univ. Gottingen, Humboldtalle 1, D-3400 Gottingen, W. Germany). *Res. Exp. Med.* 171(1):13-24; 1977.

The mechanism responsible for hyperabsorption of oxalate in patients with ileal resection was investigated by studying the intestinal transport of oxalic acid by an *in vitro* technique in rat intestine. Oxalic acid was absorbed by a mechanism of simple passive diffusion. The rate of absorption decreased from the colon to the duodenum (colon>ileum>jejunum>duodenum). Bile acids (glycocholic acid, 10^{-2} M; taurocholic acid, 10^{-2} M; deoxycholic acid, 5×10^{-3} M) enhanced oxalic acid absorption in the large and small intestine, and the extracellular space was increased by glycocholic acid and chenodeoxycholic acid (10^{-2} M). Calcium (10^{-2} M), however, markedly decreased mucosal-serosal transport of oxalic acid. Cholestyramine (20 mg/ml), known to reduce oxalate excretion in hyperoxaluria associated with ileal resection, did not directly affect absorption of oxalic acid but decreased the enhanced absorption of oxalic acid induced by bile acids. The results suggest that the beneficial therapeutic effect of cholestyramine in hyperoxaluria is mediated by its bile acid binding activity rather than by direct binding of oxalic acid.

5704 HYPEROXALURIA CORRELATES WITH FAT MALABSORPTION IN PATIENTS WITH SPRUE. (Eng.) McDonald, G. B.; Earnest, D. L.; Admirand, W. H. (Veterans Admin. Hosp., Medical Service, 4435 Beacon Ave. South, Seattle, WA 98108). *Gut* 18(7): 561-566; 1977.

The hypothesis that enhanced dietary oxalate absorption in patients with severe ileal dysfunction is associated primarily with fat malabsorption was tested in four patients with sprue and in two patients with dermatitis herpetiformis and sprue-like jejunal histology. Hyperoxaluria was present in all patients with sprue when fat malabsorption was severe. Urinary oxalate excretion decreased in two of the three patients with celiac sprue when their fat malabsorption had improved after 3 months of dietary gluten restriction. Neither patient with dermatitis herpetiformis and sprue had steatorrhea. In these latter patients, urinary oxalate excretion was always within normal limits. A significant positive linear relationship ($y=28.25 + 4.84x$; $r=0.82$; $p<0.01$) was demonstrated between fecal fat and urinary oxalate excretion. The results support the concept that severe malabsorption of dietary fat plays a primary causative role in enteric hyperoxaluria.

5705 CHARACTERISTICS OF THE IMMUNE RESPONSE IN A PATIENT WITH WHIPPLE'S DISEASE. (Eng.) Clancy, R.; Muckle, T. J.; de Jesus, D.; Stevens, D. (Royal Prince Alfred Hosp., Camperdown, NSW 2050, Australia). *Aust. N.Z. J. Med.* 7(3):294-298; 1977.

The effect of antibiotic therapy on the immune status of a patient with Whipple's disease was investigated, and the specific immune response cell wall-deficient form of an alpha-hemolytic streptococcus (αHS) isolated from this patient was studied. Thymus-derived lymphocyte numbers were reduced, and cutaneous anergy was present. Auto antibodies directed against smooth muscle and mitochondria were detected. These abnormal parameters became normal following therapy with tetracycline (1 g/day). The specific immune response to the αHS was characterized by IgA antibody and lymphocyte sensitization. The latter was detected as antigen-induced lymphocyte stimulation and antigen-induced leukocyte inhibition factor (LIF) production. Antibiotic therapy was associated with a fall in antibody titer and reduced LIF production. No defect in neutrophil function was found. These results are consistent with the postulates that immunological abnormalities in Whipple's disease are secondary to infection and that the primary abnormality is an unusual pathogenic bacterium.

5706 DISACCHARIDE CONSUMPTION AND MALABSORPTION IN CANADIAN INDIANS. (Eng.) Ellestad-Sayed, J. J.; Haworth, J. C. (Dept. Pediatrics, Univ. Manitoba, 770 Bannatyne Ave., Winnipeg R3E 0W3, Canada). *Am. J. Clin. Nutr.* 30(5): 698-703; 1977.

5707 INDIVIDUAL SENSITIVITY TO LACTOSE IN LACTOSE MALABSORPTION. (Eng.) Gudmand-Hoyer, E.; Simony, K. (Copenhagen County Hosp. in Gentofte, DK-2900 Hellerup, Denmark). *Am. J. Dig. Dis.* 22(3):177-181; 1977.

See also, 5510, 5556, 5612, 5648, 5657, 5669, 5674, 5685, 5690, 5716, 5783, 5900, 5944.

5708 BENIGN PNEUMOPERITONEUM AFTER FIBEROPTIC COLONOSCOPY: A PROSPECTIVE STUDY OF 100 PATIENTS. (Eng.) Ecker, M. D.; Goldstein, M.; Hoexter, B.; Hyman, R. A.; Naidich, J. B.; Stein, H. L. (Veterans Admin. Hosp., West Haven, CT 06516). *Gastroenterology* 73(2):226-230; 1977.

The frequency of asymptomatic colonic perforation was investigated in 100 consecutive unselected patients undergoing both diagnostic and therapeutic fiberoptic colonoscopy. All patients received frontal chest and supine and erect abdominal radiographs before, immediately after, and 24 hr after colonoscopy. Blood counts, serum amylase, creatine phosphokinase, LDH, SGPT, and SGOT were also determined. There was only one positive case of pneumoperitoneum. The patient was a 37-yr-old woman in whom the colonoscope could not be passed above 50 cm despite manipulation and air insufflation, due to fixation and angulation of the colon. The mucosa up to this level was hyperemic and friable, and multiple small erosions were noted. The patient was completely asymptomatic after the procedure, and her vital signs were stable. Approximately 8 hr later, she developed a fever with minimal midabdominal discomfort. She became afebrile and asymptomatic after complete restriction of p.o. intake and administration of i.v. fluids and antibiotics. The amount of free intraperitoneal air decreased over the next 72 hr. There was no significant change in either the blood count or enzyme levels when the pre- and postcolonoscopic values were compared. This study suggests that the incidence of colonic perforation after fiberoptic colonoscopy is low and may occur with minimal or no clinical evidence suggesting perforation.

5709 EFFECT OF LOPERAMIDE ON FECAL OUTPUT AND COMPOSITION IN WELL-ESTABLISHED ILEOSTOMY AND ILEORECTAL ANASTOMOSIS. (Eng.) Tytgat, G. N.; Huibregtse, K.; Dagevos, J.; Van Den Ende, A. (Wilhelmina Gasthuis, Amsterdam, Netherlands). *Am. J. Dig. Dis.* 22(8):669-676; 1977.

The quantitative effects of loperamide on several parameters of fecal composition and output were assessed in seven patients with an ileorectal anastomosis and in seven patients with an ileostomy. Loperamide (two 2-mg capsules, t.i.d.) or placebo was administered in a double-blind study in two randomly assigned, successive 7-day periods. Loperamide significantly decreased the daily volume (-29.2%), wet weight (-29.2%), water content (-5.5%), and fecal excretion rate (-28%) and significantly increased the bulk density (+40%) and viscosity (+285%) of the fecal collections. Electrolyte loss was significantly diminished with loperamide: daily sodium and chloride outputs were significantly decreased (-42.5% and -31%, resp.) and daily calcium, phosphate, and potassium outputs were slightly decreased. Sodium concentration significantly decreased (-12.4%), while potassium and calcium concentrations significantly increased (+12.5% and +19.2%, resp.). The phosphate concentrations increased slightly, and the chloride concentrations slightly decreased. The sodium/potassium ratio was significantly reduced (-45.5%). No effect on fecal dry weight or on lipid or bile acid outputs was observed. The fecal potassium concentration and output were significantly higher, and the sodium/potassium ratio was significantly lower in patients with an ileorectal anastomosis than in patients with ileostomy. This group also showed a tendency to slightly lower fecal volume, wet weight, water content, fecal excretion rate, sodium concentration, and output. The therapeutic efficacy of loperamide was comparable in both patient groups. The results were rated "excellent" in three patients, "good" in seven, "questionable" in three, and "poor" in one. No adverse effects attributable to loperamide were observed. All patients reported feeling better during treatment and preferred the active drug period to the placebo period.

5710 ACTINOMYCOSIS OF THE COLON. (Ita.) Campanelli, A.; De Simone, G.; Negrone, G.; Renda, F.; Rispoli, G.; Vetrano, G. (Regionale Ospedaliero Generale, Ospedali Riuniti di Napoli, Divisione Chirurgia D'Urgenza dell'Ospedale A. Cardarelli, Naples, Italy). *Rass. Int. Clin. Ter.* 57(5):310-316; 1977.

A case study of a 60-yr-old woman with actinomycosis of the colon is presented. The patient was treated by surgical intervention. Diagnosis of actinomycosis of the colon was made by histological examination. Treatment consisted of 10^6 U of penicillin G/day for 2 weeks. Two susbequently repeated acute infectious episodes, also caused by actinomycetes, were also treated with penicillin G. The patient has recovered and is now in good health. It is concluded that although actinomycosis of the colon is a rare disease, the condition should be considered when making differential diagnoses of diseases of the colon.

5711 GASTROINTESTINAL CANCER--COLON (SURGERY-RADIOTHERAPY): THE ROLE OF RADIATION THERAPY IN THE MANAGEMENT OF RECTOSIGMOID CANCER. (Eng.) Johnson, R. J. R. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263). *Cancer* 40(1):595-603; 1977.

The epidemiology, incidence, etiology, screening procedures, surgery, and the role of radiation therapy in the management of colorectal cancer are reviewed. During the last decade, the generally accepted treatment for Duke's B and C carcinoma of the colon has been surgery followed by chemotherapy. Gross survival statistics and a large randomized trial show that 5-fluorouracil therapy has not increased survival. No drug or combination of drugs has as yet lengthened survival when used in the adjuvant situation. The improvement in regional tumor control and a decrease in distal metastases reported in an unrandomized study in 1956 has not been reflected in the gross survival statistics, despite the fact that a large percentage of surgeons has adopted this superior surgical technique. The widespread use of carcinoembryonic antigen does not appear to have affected the survival figures, probably because large volumes of tumor associated with incurable disease are required before the test becomes positive. Adjuvant radiotherapy has been used in a very small number of institutions despite the promise suggested for this modality by radiotherapy results published in the 1950's. The therapeutic gain, which may be expected to be shown in the current randomized adjuvant trials utilizing preoperative or postoperative radiotherapy, should not be expected to exceed 10-20%, since radiotherapy may only decrease regional tumor recurrence; however, preoperative radiation may also decrease the metastasis rate. Large changes in survival of advanced rectal cancer can be expected only when chemotherapeutic agents capable of permanently controlling microscopic metastatic disease can be used in conjunction with radiation to control regional disease. Both surgical electrocoagulation and intracavitary radiotherapy have produced a high cure rate in selective Duke's A carcinoma of the rectum. Radiation therapy should be considered as an alternative primary modality whenever surgery is refused or contraindicated.

5712 ELECTIVE POSTOPERATIVE RADIOTHERAPY FOR LOCALLY ADVANCED COLORECTAL CANCER: A PRELIMINARY REPORT.

(Eng.) Turner, S. S.; Vieira, E. F.; Ager, P. J. Alpert, S.; Efron, G.; Ragins, H.; *et al.* (Long Island Coll. Hosp., Brooklyn, NY). *Cancer* 40(1):105-108; 1977.

The role of elective postoperative irradiation was studied in patients with locally advanced colorectal carcinoma. From October 1972 to December 1975, 40 patients at high risk for local recurrence (B_2 and C) received postoperative radiotherapy. Lesions that were located in the rectum and in the rectosigmoid and low sigmoid colon were given 4,600 rads in 4.5 weeks through an inverted T-shaped field that encompassed the pelvic and paraortic nodes. Patients with tumors located above mid-sigmoid were treated to the entire abdominal cavity by the moving strip technique. Of 19 patients with rectal and rectosigmoid lesions, 14 are alive without evidence of disease. Two had local recurrences in the treated area. Of 21 patients with lesions above the mid-sigmoid, 4 have failed locally, while 11 are alive without evidence of disease. One of these 40 patients died of radiation enteritis. Although the follow-up period is short, the results suggest that a moderate dose of radiation may prevent local recurrence in patients with locally advanced colorectal cancer.

5713 CANCER MARKERS IN PATIENTS RECEIVING CHEMOTHERAPY FOR COLORECTAL CANCER: A PRELIMINARY REPORT.

(Eng.) Bullen, B. R.; Cooper, E. H.; Turner, R.; Neville, A. M.; Giles, G. R.; Hall, R. (St. James Univ. Teaching Hosp., Leeds, England). *Med. Pediatr. Oncol.* 3(3):289-300; 1977.

Carcinoembryonic antigen (CEA), hepatic function marker enzymes, and four acute phase reactant proteins (haptoglobin, α_1-antitrypsin, α_1-acid glycoprotein, and prealbumin) were determined as a routine monitoring system in patients with colorectal cancer receiving chemotherapy. In 18 patients with advanced lesions who survived at least 3 months of treatment, the markers predicted progression in 92% of 25 incidents of progression; the mean lead time was 2.8 months. A rising CEA was only present in 28%, but in these patients, it gave a mean lead time of 4 months. Among 14 patients with minimal residual disease, progression to clinically detectable disease has occurred in 9. In these cases, the markers predicted progression, wit a mean lead time of 6 months; in a further six patients, the markers have indicated progression, but as yet the disease is not detectable, the mean lead time being at least 8.6 months. CEA and the liver enzyme markers are the most sensitive indicators of progression of the minimal residual disease group.

5714 CELLULAR IMMUNITY IN PATIENTS WITH COLORECTAL ADENOCARCINOMA MEASURED BY AUTOLOGOUS LEUKOCYTE MIGRATION INHIBITION.

(Eng.) Elias, E. G.; Elias, L. L.; Didolkar, M. S.; Hebel, J. R. (Univ. Maryland Hosp., 22 S. Greene St., Baltimore, MD 21201). *Cancer* 40(2):687-692; 1977.

Tumor-specific cell-mediated immunity was studied *in vitro*, using the leukocyte migration inhibition test (LMT) in 62 patients with various stages of colorectal adenocarcinoma. These patients underwen exploratory laparotomy for curative or palliative resections and were staged surgically and pathologi ally. Autologous tumor and mucosa were obtained from their surgical specimens, and its homogenates were used for autologous LMT initially, i.e., on the day of surgery, and stored for the follow-up studies utilizing freshly obtained autologous peripheral blood. Patients with localized or regional disease were initially hypersensitized to their tumors when compared with those with disseminated disease. However, the follow-up studies expressed loss of such hypersensitivity. This could explain a possible mechanism for the development of metastasis and might provide an "escape" mechanism for the tumor immune response in the host on the cellular level. These findings might reflect on immunotherapy in patients with regional or local disease after their curative surgery. For passive immunization, the lymphocytes should be obtained from these patients prior to surgery. Active or passive immunization could then be administered in the postoperative period and monitored by LMT.

5715 CEA-TEST ON COLONOSCOPIC LAVAGE FLUID AS A SUBSIDIARY TECHNIQUE IN EVALUATING PRECANCEROUS COLONIC CONDITIONS.

(Eng.) Rossini, F. P.; Ferrari, A.; Droetto, G. (Ospedale San Giovann Molinette, Corso Bramante, 88, 10125 Torino, Italy *Rend. Gastroenterol.* 9(1):28-31; 1977.

The value of carcinoembryonic antigen (CEA) determination in fluid collected by means of colonic lavage during colonoscopy was studied in 54 patient with a normal large bowel, 87 with colonic carcinom

96 with ulcerative colitis, 18 with Crohn's disease of the colon, and 21 with polyposis. The CEA levels in the lavage fluid of the normal subjects were less than 20 ng/ml in all cases. The mean CEA level in the patients with carcinoma was 195 ng/ml, and levels of 20 ng/ml or lower were found in only 22 carcinoma patients. In the 18 patients with ulcerative colitis for less than 5 yr, the mean CEA level was 19 ng/ml, while that in patients with disease of longer duration, the level was 150 ng/ml. The level in patients with Crohn's disease for less than 5 yr was 15 ng/ml, while that in patients with disease of longer duration was 150 ng/ml. In 18 patients with uncomplicated polyposis, the mean level was 8.5 ng/ml, while that in the 3 patients in whom familial polyposis progressed to carcinoma was 220 ng/ml. The measurement of CEA in colonic fluids seems to be useful in monitoring the course of diseases with a known potential for malignancy and in the diagnosis of large bowel cancer.

5716 COLITIS, PERSISTENT DIARRHEA, AND SOY PROTEIN INTOLERANCE.

(Eng.) Halpin, T. C.; Byrne, W. J.; Ament, M. E. (Univ. California at Los Angeles Center for the Health Sciences, Los Angeles, CA 90024). *J. Pediatr.* 91(3):404-407; 1977.

Four infants with vomiting, diarrhea, hematochezia, and weight loss of more than 10% were studied for the presence of suspected soy protein intolerance. Laboratory abnormalities included anemia (3 patients), acidosis (3), hypoalbuminemia (3), hypernatremia (1), hyponatremia (3), and mild eosinophilia (2). Symptoms developed between 3 hr and 5 days after systematic testing with increasing volumes of soy formula. After challenge with soy protein formula, proctosigmoidoscopy and rectal biopsy were performed within 24 hr of developing stools with gross blood. Proctosigmoidoscopy showed both spontaneous and induced friability and loss of vascular pattern in mucosa. Rectal biopsy showed acute colitis with crypt abscesses, depletion of mucus from rectal glands, and polymorphonuclear leukocytes within the lamina propria. Soy protein-induced colitis should be suspected in infants presenting with persistent bloody diarrhea after being fed soy formula.

5717 GLUCOSAMINE SYNTHETASE ACTIVITY OF THE COLONIC MUCOSA IN MEMBRANOUS COLITIS.

(Eng.) Goodman, M. J.; Kent, P. W.; Truelove, S. C. (Dept. Medicine, Univ. Chicago, Chicago, IL). *Gut* 18(3):229-231; 1977.

Glucosamine synthetase activity was measured in rectal biopsies of four patients with membranous colitis. Three patients had received antibiotics prior to the onset of the disease. A rectal biopsy was taken and assayed for the enzyme at the time of diagnosis and after a 5-day i.v. course of 0-60 mg of prednisolone-21-phosphate daily. The patients then received p.o. prednisolone and prednisolone retention enemas for a further 6 weeks, and biopsies were taken on the 10th day and at weeks to 3 months. All patients showed complete clinical and sigmoidoscopic recovery. In comparison to a previously determined normal glucosamine synthetase level (i.e., 13.77 ± 3.97 U), the peak levels in each patient were 36.0, 27.0, 31.7, and 20.5 U, resp.; the first two peak levels occurred at the time of diagnosis, and the remaining two levels occurred within 10 days of beginning treatment. The first three patients showed a fall in enzyme levels after the peak was reached. These high levels may be related to the mucous hypersecretion typical of membranous colitis, but it seems more likely that they represent the healing of the mucosa.

5718 BACTERIOLOGICAL STUDIES IN A PATIENT WITH ANTIBIOTIC-ASSOCIATED PSEUDOMEMBRANOUS COLITIS.

(Eng.) Allen, S. D.; Dunn, G. D.; Page, D. L.; Wilson, F. A. (Center for Disease Control, Enterobacteriology Branch, 1-B341, Atlanta, GA 30333). *Gastroenterology* 73(1):158-163; 1977.

Detailed aerobic and anaerobic bacteriological studies were carried out on the operative specimen from a patient with antibiotic-associated pseudomembranous colitis, and data are presented on the toxigenicity, tissue invasiveness, lethality for mice, and antibiotic susceptibility of the bacteria isolated. There were approximately 10^{11} facultatively anaerobic bacteria, but less than 10^{5} obligate anaerobes per gram of involved colonic tissue. Fourteen isolates of *Escherichia coli*, three isolates of *Pseudomonas aeruginosa*, and two isolates of *Streptococcus fecalis* were identified. All *E. coli* isolates were resistant to clindamycin, penicillin, and ampicillin, and *P. aeruginosa* was resistant to every antibiotic the patient had received (cefazolin, clindamycin, kanamycin, procaine penicillin, gentamycin, ampicillin, and chloramphenicol). *S. fecalis* was resistant to clindamycin, kanamycin, and gentamicin. Examinations of *E. coli* for heat-labile and heat-stable enterotoxins and tissue invasiveness were negative, and enterotoxin tests on the *P. aeruginosa* isolates were negative. Inoculation of mice with the bacterial isolates revealed no unusual pathogenicity. These findings suggest that antibiotic-associated colitis is associated with a marked loss in anaerobic colonic flora, but the colitis could not be explained by the presence of enterotoxins, tissue invasiveness, and pathogenicity of remaining microorganisms.

5719 PROPHYLACTIC SYSTEMIC ANTIBIOTICS IN COLORECTAL SURGERY.

(Eng.) Feathers, R. S.; Sagor, G. R.; Lewis, A. A. M.; Amirak, I. D.; Noone, P. (Royal Free Hosp., Pond St., Hampstead, London NW3 2QG, England). *Lancet* 2(8027):4-8; 1977.

The prophylactic value of gentamicin combined with either lincomycin or metronidazole was investigated in 52 patients undergoing colorectal surgery. Gentamicin (1.6 mg/kg) was initially given every 8 hr i.m. or i.v., and then according to serum concentrations, to achieve a peak of between 5 and 10 μg/ml. Metronidazole was given as a 1-g suppository every 8 hr together with gentamicin; in cases of low anterior resection, it was given i.v. (500 mg). In 25 untreated controls, the sepsis rate was 48%, and one death was attributable to sepsis. There was only one case of sepsis (a superficial infection of the lower abdominal wound in a patient treated with gentamicin and metronidazole) in the treated group, and no deaths attributable to sepsis occurred. The combination of gentamicin and lincomycin was effective against sepsis, but pseudomembranous colitis developed in 2 of the 14 patients treated with this combination, one of these patients died. The gentamicin/metronidazole combination had no toxic side-effects. The results show that the combination of gentamicin and metronidazole is effective and safe in the prophylaxis of infection in colorectal surgery.

5720 COLONIC PROPULSION IN DIVERTICULAR DISEASE, IDIOPATHIC CONSTIPATION, AND THE IRRITABLE COLON SYNDROME.

(Eng.) Kirwan, W. O.; Smith, A. N. (Western General Hosp., Edinburgh, Scotland). *Scand. J. Gastroenterol.* 12(3):331-335; 1977.

Colonic intraluminal pressure and intestinal transit time were measured simultaneously to assess colonic motility indexes in 15 patients with uncomplicated diverticular disease, 4 patients with idiopathic constipation, and 7 with the irritable colon syndrome. The patients were also studied after the ingestion of bran to ascertain whether there was any preferential action on pressure or intestinal transit. The transit time in diverticular disease was increased (68 ± 14 hr) in comparison with transit time in normal subjects (23 ± 1 hr); after bran, this was reduced to 32 ± 6 hr ($p<0.05$). The transit time was prolonged in idiopathic constipation (93 ± 23 hr) and in the irritable colon syndrome (59 ± 18 hr); the effect of bran was more pronounced ($p<0.05$) in the constipated patients than in the patients with irritable colon (not significant). The mean transit times in the right colon, transverse colon, splenic flexure, and rectosigmoid of 12 diverticular disease patients were 25 ± 5, 24 ± 0, 26 ± 2, and 29 ± 4 hr, resp.; bran decreased these times significantly to 16 ± 2 hr ($p<0.0025$), 16 ± 2 hr ($p<0.0025$), 16 ± 2 hr ($p<0.0005$), and 18 ± 2 hr ($p<0.0025$), resp. A comparable time was taken in each zone for idiopathic constipation and for irritable colon; these were also reduced by bran, but to a lesser extent. In the 15 patients with diverticular disease, the basal colonic motility index was reduced from 1,848 ± 387 to 764 ± 214 ($p<0.0125$) by bran; the postprandial colonic motility index fell from 2,566 ± 415 to 1,771 ± 264 ($p<0.10$) after bran, and the prostigmine motility index fell from 5,298 ± 456 to 3,968 ± 511 ($p<0.05$); similar changes occurred in the irritable colon syndrome ($p<0.05$) but not in idiopathic constipation. The diverticular disease patients fell into two groups: 5 with an extremely long transit time and a moderately raised intraluminal pressure and 10 with a normal transit time and an extremely raised intraluminal pressure; this proportionality was maintained after bran. Up to certain physiologic levels of intraluminal pressure, an increase in pressure may serve to restrain the propulsion of the intraluminal contents; but when the pressure rises above this level, a further increase results in propulsion of the contents.

5721 HIRSCHSPRUNG'S DISEASE COMBINED WITH AGA
LIONOSIS AND SO-CALLED NEURONAL COLONIC
PLASIA (DYSGANGLIONOSIS COLICA).

(Ger.) Gullotta
F.; Straaten, G. (Institut Neuropathologie der Uni
versitat, 5300 Bonn-Venusberg, W. Germany). *Z. Ki
derchir.* 20(1):42-49; 1977.

Hirschsprung's disease with aganglionosis and neuronal colonic dysplasia was diagnosed in a 2-yr-ol
boy. At the age of 3.5 weeks, when Hirschsprung's
disease was suspected, a double transverse colosto
was inserted during toxic colitis with paralytic ileus. Initially, an end-to-end anastomosis between the proximal descending colon and the ampull
recti 4 cm above the anus was performed, followed by several bougienages of the deep anastomosis and widespread sphincter extension. Ten months later, resection of the double transverse anus and a portion of the transverse colon, termino-terminal large intestine anastomosis, and an appendectomy were performed. However, 3 weeks after surgery, colitis with diarrhea and fever developed. Colon contrast examination revealed pathological changes in the descending colon in the fold reliefs of the mucosa, atypical slow peristalsis and delayed empt
ing of the large intestine. Nutritional therapy w
Vivasorb for 50 days was started. Histological an
enzyme histochemical examination of the first rese
tion showed aganglionosis in the transverse colon with a high acetylcholinesterase activity in the m
cosa and submucosa. In the most distal part of th
resected intestinal section, individual ganglion cells or small plexus were present. The second op
ation showed that, in the proximal part, the myent
ic plexus had giant and hypertrophic multinucleate
ganglion cells similar to those described by Meyer
Ruge as neuronal dysplasia. These findings emphas
the complex malformation of this syndrome, which h
also been called "dysganglionosis colica." At the time of report the child was 5 yr old with normal development.

5722 ABOUT THE SO-CALLED ISCHEMIC-ULCERATIVE INNERWALL LESION OF THE BOWELS PROXIMAL TO INTESTINAL STENOSES.

(Ger.) Stellamor, K.; Redtenbacher, M.; Kosak, D.; Karobath, H. (Krankenanstalt Rudolfstiftung, Juchgasse 25, A-1030 Wien, Austria). *Fortschr. Roentgenstr.* 126(6):556-
559; 1977.

Ischemic ulcerative innerwall lesion of the bowel proximal to intestinal stenoses was diagnosed in seven patients, aged 6-87 yr old. Stenoses were caused by carcinoma of the colon in five cases and by chronic recurrent inflammatory changes due to diverticulitis of the sigmoid colon in two cases. Suture complications occurred in two patients afte
removal of stenoses. Four of the seven patients died; two died of total necrosis of the small or large intestines, and one patient each died of car

ioma of the thyroid gland or massive infarction.
ree patients survived without complications after
rgery. Pathological-anatomical findings revealed
ngitudinal and linearly situated ulcers with a
prinoid and purulent bases surrounded by edema-
us or rigid mucosa. Histologically, the ulcers
ached up to the muscularis propria and had a
prinoid/necrotic layer. The mucosal borders
owed inflammatory, pseudopolyp formations and
ojections. Thromboses were also noted in the
r, thin-walled venous vessels of the submucosa
the ulcer regions. The venous vessels were di-
ted and partially thrombosed. X-ray pictures were
aracterized by typical signs of an ulcerative
testinal wall process with high-grade stenoses.

23 IDIOPATHIC PROCTITIS. I. THE MORPHOLOGY OF PROXIMAL COLONIC MUCOSA AND ITS CLIN-
AL SIGNIFICANCE. (Eng.) Das, K. M.; Morecki, R.;
ir, P.; Berkowitz, J. M. (Albert Einstein Coll.
dicine, 1300 Morris Park Ave., Bronx, NY 10461).
. *J. Dig. Dis.* 22(6):524-528; 1977.

e extent of mucosal disease in 31 symptomatic
tients with idiopathic proctitis was evaluated
the microscopic examination of mucosal samples
tained during colonoscopy from different levels
the colon; the extent of mucosal lesions was then
rrelated with the clinical course. Mucosal biopsy
ecimens were considered to reflect inflammatory
sease when they showed at least two of the follow-
g abnormalities: (1) increased numbers of inflam-
tory cells in the lamina propria, (2) glandular
crosis, (3) crypt abscesses, (4) ulcerations, or
depletion of goblet cells and mucosal atrophy.
ong eight patients with newly diagnosed untreated
octitis with symptoms for less than 6 months,
ree showed involvement in portions of large in-
stine up to the transverse colon; in the remaining
ve, involvement was limited to the rectosigmoid
nction. Among nine patients with diagnosed idio-
thic proctitis for over 1 yr who had a long per-
l of remission (up to 12 months) prior to the
test episode, only one had involvement of the
ansverse colon. In contrast, 12 of 14 patients
h an established diagnosis of idiopathic proc-
tis for over 1 yr who were either having contin-
us symptoms or relapses at 2- to 4-month inter-
s had involvement up to the transverse colon.
tients in whom microscopic mucosal abnormalities
re limited to the most distal 20 cm of colon gen-
lly responded well to hydrocortisone enemas and
. sulfasalazine (2-3 g/day), but patients with
e extensive abnormalities responded poorly to
s regimen; some only partially responded after
e addition of p.o. corticosteroids. The results
ggest that idiopathic proctitis may comprise at
st two disease processes distinguished by the
tent and localization of microscopic mucosal
normalities.

24 VOLVULUS OF THE SIGMOID COLON. (Eng.)
Khoury, G. A.; Pickard, R.; Knight, M.
. George's Hosp., London, England). *Br. J. Surg.*
(8):587-589; 1977.

The clinical presentation and treatment of 31 consecutive patients with sigmoid volvulus were reviewed to improve treatment and prognosis. Nearly half of these patients had a history of mental illness, and one-third of all patients were chronically constipated. The main clinical features of abdominal pain and gross abdominal distension had been present for an average of 8 days before hospitalization. The presence of nonviable bowel was more difficult to establish than was the diagnosis of volvulus. A silent abdomen was the most valuable indication of the presence of gangrenous bowel. Conservative measures, including sigmoidoscopy and therapeutic barium enema, successfully reduced the volvulus in 6 of 11 cases. In 24 patients undergoing surgery (sigmoid colectomy and primary anastomosis, 6; Paul Mikulicz procedure, 10; Hartman's operation, 3), the procedure associated with the lowest mortality was sigmoid resection with end-to-end anastomosis. The overall mortality was 35%.

5725 RECTAL DUPLICATION PRESENTING AS PELVIC HERNIA IN A NEONATE: CASE REPORT. (Eng.) Khan, O.; Eckstein, H. B. (Hosp. Sick Children, Great Ormond St., London, WC1N 3JH, England). *Z. Kinderchir.* 21(1):95-98; 1977.

5726 AN IMPROVED SNARE FOR REMOVAL OF RECTOSIGMOID POLYPS. (Eng.) Bisordi, W.; Morgan, B.; Smith, D.; Kleinman, M. S. (Strong Memorial Hosp., Rochester, New York, NY 14642). *Am. J. Dig. Dis.* 22(7):650-655; 1977.

5727 SPONTANEOUS PERFORATION OF THE COLON: A POTENTIAL COMPLICATION OF CHRONIC RENAL FAILURE. Bartolomeo, R. S.; Calabrese, P. R.; Taubin, H. L. (114 State St., Bridgeport, CT 06604). *Am. J. Dig. Dis.* 22(7):656-657; 1977.

LARGE INTESTINE

Ulcerative Colitis

5757 ACUTE SPONTANEOUSLY RECOVERING ULCERATING COLITIS (ARUC): REPORT OF 6 CASES. (Eng.) Bonfils, S.; Hervoir, P.; Girodet, J.; Le Quintrec, Y.; Bader, J. P.; Gastard, J. (Hopital Bichat, 170 Boulevard Ney, 75877 Paris Cedex 18, France). *Am. J. Dig. Dis.* 22(5):429-436; 1977.

The cases of six patients with an unclassifiable, extensive, ulcerating colitis that had a spontaneously reversible course are presented. The patients included four women (aged 20-23 yr) taking p.o. contraceptives and a 69-yr-old woman and a 51-yr-old man, neither of whom had any specific drug history. No previous disease and no precipitating factors were found. Appendectomy was performed prior to the diarrhea occurrence in three cases. Bacteriological and parasitological studies were negative in all cases. All patients had a febrile nonbloody diarrhea. Radiological involvement of the whole colon with superficial ulcerations and preservation of haustra occurred in all patients, and rectal and ileal ulceration was present in only one patient each. Anal lesions occurred in only one patient. The clinical symptoms remitted within 1 month in all patients, and radiological abnormalities disappeared within 2-5 months. Treatment consisted of a low-fiber diet, water and electrolyte replacement, and various intestinal antiseptics (salicylazosulfapyridine, sulfaguanidine, Intetrix). In four cases, corticosteroids were given in the absence of a specific diagnosis. The patients have experienced no symptoms during follow-up periods between 18 months and 5 yr. These cases could represent a new entity or could be a particular form of Crohn's disease of the colon, with delayed diagnostic pathological features.

5758 PRELIMINARY FINDINGS ON GLYCOCALYX IN COLON EPITHELIAL CELLS IN NORMAL SUBJECTS AND IN PATIENTS WITH ULCERATIVE COLITIS. (Ita.) Ceralli, F.; Familiari, G.; Marinozzi, G.; Muccioli-Casadei, D. (Istituto di Anatomia Umana Normale, Universita di Roma, Rome, Italy). *Bull. Soc. Ital. Biol. Sper.* 52(12):886-891; 1976.

An investigation was made of the glycocalyx in patients with ulcerative colitis and in normal subjects. Biopsy material was obtained from patients with clinically evident ulcerative colitis and patients suspected of having the disease. Some of these latter patients were subsequently shown to be normal and served as controls. In normal subjects, the glycoprotein cellular mantle was well-defined and the cells were contiguous. In patients with colitis, the mantle was thin, not contiguous, and irregular. The glycocalyx in colitis patients was almost completely absent. Where it could be seen, it was irregular and a large portion of the microvilli had been lost. Microvilli that were present were highly irregular in appearance. In normal patients, the glycocalyx formed a continuous layer on the surface of the microvilli, which were normal in appearance. It is suggested that the pathological process of ulcerative colitis may be due to a viral agent.

5759 RECTAL MUCOSAL ADRENERGIC INNERVATION AND ENTEROCHROMAFFIN CELLS IN ULCERATIVE COLITIS AND IRRITABLE COLON.

(Eng.) Kyosola, K.; Penttila, O.; Salaspuro, M. (Maria Hosp., SF-00180 Helsinki 18, Finland). *Scand. J. Gastroenterol.* 12(3):363-367; 1977.

The glyoxylic acid-induced fluorescence histochemical technique was used to determine whether there are alterations in the intrinsic adrenergic innervation and the enterochromaffin cells (EC) in ulcerative colitis and the irritable colon syndrome. Rectal mucosal biopsies of 13 patients with ulcerative colitis, 7 patients with the irritable colon syndrome, and 7 controls were studied. In comparison with control biopsy specimens, specimens from patients with ulcerative colitis had significantly increased adrenergic nerve network densities ($p<0.01$). The mean diameter of the varicosities was also increased, as was the number of varicosities per given length of axon ($p<0.001$). The intensity of the fluorescence of varicosities of comparable size was significantly increased ($p<0.001$), and the number of EC was significantly decreased ($p<0.01$). In contrast, the number of EC in the irritable colon syndrome was significantly increased ($p<0.05$) compared with that in controls. The results suggest that biogenic amines are involved in both ulcerative colitis and the irritable colon syndrome.

5760 EMOTIONAL FACTORS IN INFLAMMATORY BOWEL DISEASE.

(Eng.) Zisook, S.; DeVaul, R. A. (Univ. Texas Medical Sch. at Houston, Houston, TX 77030). *South. Med. J.* 70(6):716-719; 1977.

Emotional factors influencing the pathogenesis and the course of inflammatory bowel disease are discussed, and the cases of three patients are reviewed. The most widely studied emotional factors related to the cause and pathogenesis of inflammatory bowel diseases include personality constellations and specific stress reactions. Some investigators describe the ulcerative colitis personality as an "obsessive-compulsive personality," while others doubt the specificity of personality configuration with inflammatory bowel diseases and maintain that the disease itself may affect the patient's personality. The stress situation that is most often cited as influencing the onset and exacerbations of inflammatory bowel diseases is the loss (actual or threatened) of an important love relationship. Examples include an 18-yr-old man who developed his first attack of ulcerative colitis shortly after both of his parents were killed, a 21-yr-old woman who felt she could not cope with college and examinations without the help and support of her parents, and a 25-yr-old man who developed colitis shortly before his marriage to a women who was not accepted by his parents. Problems encountered in the management of the disease include the patient's denial of illness or his overtly assuming a sick role, the meaning of the symptoms to the patient, managing the patient's feelings of loss or rejection, and managing the patient's feeling of diminished self-control. Inflammatory bowel diseases are not caused by emotional conflicts, but emotional factor influence both the pathogenesis and course of the illnesses. Establishing a trusting physician-patient relationship is important in treatment.

5761 CANCER IN CHRONIC ULCERATIVE COLITIS: DIAGNOSTIC ROLE OF SEGMENTAL COLONIC LAVAGE.

(Eng.) Katz, S.; Katzka, I.; Platt, N.; Hajdu, E. O.; Bassett, E. (1300 Union Turnpike, New Hyde Park, NY 11040). *Am. J. Dig. Dis.* 22(4): 355-364; 1977.

The use of segmental colonic lavage for the detection of cancer in 74 patients with chronic ulcerative colitis is reported. Approximately 500-1,000 cm^3 saline was introduced as a pulsatile lavage through a polyethylene catheter powered by a commercially available dental irrigating unit in the biopsy channel of a colonoscope. Fluid was retrieved simultaneously in a suction trap containing an equal volume of 95% alcohol. The aspirate was centrifuged at 2,500 revolutions/min for 15 min. Papanicolau smears were obtained from the sediment, and the remaining material was processed according to cell-block techniques and examined in tissue sections. Rectocolonic biopsies were obtained, whe possible, via rigid and flexible endoscopes. Colonic carcinoma was found in six of the above patients. Two diagnoses of malignancy were establish by cytologic smears and cell block alone. Two patients had positive mucosal biopsies and cell block One patient with a hepatic flexure carcinoma and a second patient with a malignancy proximal to a left colon stricture were missed by the above techniques Segmental lavage in areas of stricture or grossly distorted mucosa or in endoscopically inaccessible areas appears to represent a valuable adjunct in th diagnosis of carcinoma in chronic ulcerative coliti

5762 LOCALIZED TUMOR-LIKE LESIONS IN ULCERATIV COLITIS AND CROHN'S DISEASE OF THE COLON.

(Eng.) Martinez, C. R.; Siegelman, S. S.; Saba, G. P.; Diaconis, J. N.; Yardley, J. H. (Johns Hopkins Hosp., 601 North Broadway, Baltimore, MD 21205). *Johns Hopkins Med. J.* 140(5):249-259; 1977.

The roentgenographic manifestation of localized inflammatory lesions of the colon as localized tumor-like lesions is discussed, and case reports of two patients with ulcerative colitis and two patients with Crohn's disease are presented. Localized tumor-like lesions of the colon in ulcerative colitis are radiographically more often discrete and polypoid than in Crohn's disease and may be associated with stricture formation. In both of the patients with ulcerative colitis, the histologic features of the pseudopolyps were entirely benign. Narrowing of the bowel lumen adjacent to areas of pseudopolyposis was noted in both of these patients In patients with Crohn's disease of the colon, localized areas of colonic involvement can present as flat or nodular eccentric filling defects, with or without ulcers or deep fissures; their radiographic appearance is like that of a malignant gastric ulcer. Pathologically, these lesions are

t likely to consist of an elevated mound of
osa and underlying structures that are edematous
infiltrated with inflammatory cells. Ulcers
deep fissures are often found with normal mucosa
ervening; lymphoid hyperplasia, as seen in one
the two patients with Crohn's disease, is less
mon but can also occur. Such lesions may repre-
t the earliest and only finding in Crohn's
ease of the colon and may disappear upon insti-
ion of appropriate therapy or may progress into
more typical skip segments of colonic involve-
t. They are likely to be confused radiographic-
y with primary or metastatic carcinoma, lymphoma,
focal areas of ischemic colitis. In view of
higher risk of colonic carcinoma in patients
n ulcerative colitis, and to a lesser degree in
ients with Crohn's disease of the colon, it is
ommended that all such localized lesions of the
on be meticulously examined by double (air-
ium) contrast examination, colonoscopy, and bi-
ies to determine the precise nature of the dis-
er before extensive surgery is performed.

3 CONTRIBUTION OF RETROGRADE CHOLANGIOGRAPHY
IN A CASE OF PRIMARY SCLEROSING CHOLANGI-
. (Fre.) Descamps, C.; Gillain, A.; Vanheuver-
n, R.; Haot, J.; Pringot, J.; Dive, C. (Dept. de
ecine interne, Univ. catholique de Louvain, Clin.
versitaires Saint-Luc, avenue Hippocrate 10,
) Bruxelles, Belgium). *Acta Gastroenterol. Belg.*
1/2):55-65; 1977.

are case of cholestasis associated with a well
erated ulcerative colitis of 10 years' duration
described. Retrograde cholangiography permitted
iagnosis of primary sclerosing cholangitis, based
the irregular narrowing of the choledochus with
atation above this point. The ulcerative coli-
was of diagnostic significance, since 30% of
es of primary sclerosing cholangitis are asso-
ed with it. Antibiotic therapy (ampicillin,
/day; gentamicin, 40 mg/day) caused temporary
rovements during recurring bouts of icterus and
itis, but did not prevent further stenosis of
choledochus, which was evident on a repeat chol-
iography 1 yr later. A choledochojejunostomy
performed with excellent results.

PANCREAS

1 CHOLANGIOPANCREATOGRAPHY AND PANCREATIC
CYTOLOGY IN CARCINOMA OF THE PANCREAS.
;.) Wilkins, R. A.; Hatfield, A. (Northwick
: Hosp. and Clinical Res. Center, Watford Rd.,
ow, Middlesex HA1 3UJ, England). *Am. J.*
tgenol. 128(5):747-749; 1977.

The usefulness of cytologic examination of pure pancreatic juice collected at endoscopic retrograde cholangiopancreatography (ERCP) was evaluated in 23 laparotomy- or autopsy-proven cases of pancreatic carcinoma. ERCP was performed preoperatively in all cases, and the flow of pancreatic juice was stimulated by the i.v. injection of secretin (1 U/kg). The pancreatic duct was cannulated and opacified in 17 cases, and pancreatic juice cytology was obtained in all 17. Six of the 17 patients had total obstruction of the pancreatic duct, and 6 others showed extreme narrowing of the main pancreatic duct; these 12 cases were therefore thought to be highly suggestive of carcinoma. The pancreatic juice cytology revealed malignant cells in 8 of the 17 cases; all but one of the eight cases had either total obstruction or extreme narrowing of the pancreatic duct. All eight cases with positive cytology had carcinomas involving the head or neck of the pancreas. Among five patients in whom the radiologic diagnosis was equivocal (those in which the pancreatic narrowing was not as extensive as in the above 12 cases and 1 patient in whom the pancreatic duct was not visualized), cytology revealed malignant cells and confirmed the diagnosis in two. In the remaining five cases in which it was not possible to cannulate the ducts adequately, pancreatic juice cytology demonstrated malignant cells in all.

5772 CANCER AND ADVANCED PANCREATITIS OF THE HEAD OF THE PANCREAS IN THE ERCP (ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY). (Ger.)

Justich, E.; Wiedner, F.; Kratochvil, P.; Brandstatter, G. (Universitatsklinik fur Radiologie, Landeskrankenhaus Graz, A-8036 Graz, Austria). *Roentgenblaetter* 30(7):343-346; 1977.

The difficulties in the differential diagnosis of three cases each of carcinoma and chronic pancreatitis of the head of the pancreas by endoscopic retrograde cholangiopancreatography (ERCP) are presented. Patients with chronic pancreatitis showed stenosis of the common bile duct, pseudocystic cavities in the head of the pancreas, pancreatic calcification, or irregular constriction at the stenosed and dilated intrapancreatic bile duct. One patient with carcinoma also showed stenosis at the common bile duct with a kink formation and constriction of the pancreatic duct. The other two patients showed a depression with a break, stenosis, or constriction of the common bile duct. The average age of the patients with carcinoma was 65.2 yr as compared with 49.4 yr for patients with chronic pancreatitis. Due to the similarities of images seen by ERCP, additional diagnostic methods should be used to diagnose these diseases.

5773 PROSPECTIVE EVALUATION OF THE PANCREATIC SECRETION OF IMMUNOREACTIVE CARCINOEMBRYONIC ANTIGEN, ENZYME, AND BICARBONATE IN PATIENTS SUSPECTED OF HAVING PANCREATIC CANCER. (Eng.)

DiMagno, E. P.; Malagelada, J. R.; Moertel, C. G.; Go, V. L. W. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 73(3):457-461; 1977.

The suggestion that measurement of immunoreactive carcinoembryonic antigen (CEA) in pancreatic secretion may be useful in the diagnosis of pancreatic cancer was tested in 57 patients with abdominal pain, weight loss, obstructive jaundice, or unexplained pancreatitis. Using duodenal intubation and a perfusion method, the rate of pancreatic CEA secretion into the duodenum was measured under basal saline perfusion, alone and with continuous i.v. infusion of secretin (2 clinical U/kg/hr) and of cholecystokinin-pancreozymin (CCK, 15 Crick-Harper-Raper U/kg/hr); the CEA output was compared with secretion of trypsin, lipase, and bicarbonate under the same conditions. Subsequent laparotomy revealed pancreatic carcinoma in 25 patients, pancreatitis in 7, other intraabdominal malignancies in 6, and benign nonpancreatic disorders in 19. CEA output rates did not differentiate all pancreatic cancer patients from other patients in any test condition. However, pancreatic enzyme outputs were abnormal with almost 90% of cancers of the pancreatic head and with 75% of cancers of the pancreatic body and tail. For detection of pancreatic cancer, enzyme and bicarbonate outputs in response to CCK are more accurate than pancreatic CEA or bicarbonate outputs in response to secretin Since it is known that CCK-stimulated enzyme outputs can be related accurately to malabsorption, they may be preferable to bicarbonate output for assessment of pancreatic function.

5774 DUODENOSCOPY AND ENDOSCOPIC PANCREATOGRA IN PATIENTS WITH POSITIVE MORPHINE PROSTIGMINE TESTS. (Eng.)

Gregg, J. A.; Taddeo, A. E Milano, A. F.; McCartney, A. J.; Santoro, B. T.; Frager, S. H.; Capobianco, A. G. (110 Francis St., Boston, MA 02215). *Am. J. Surg.* 134(3):318-321; 1977.

The relation between pancreatic disease, an abnorm morphine prostigmine test, and endoscopic retrogra cholangiopancreatography (ERCP) was studied. Twen three patients with abdominal pain and positive morphine prostigmine tests underwent duodenoscopy and ERCP. Sixteen patients demonstrated marked or moderate ampullary stenosis. The pancreatic duct was dilated in three and stenotic in four. Ampull stenosis was confirmed in all patients who subsequently underwent sphincteroplasty. Only six patients had pancreatitis demonstrated by laboratory studies or at surgery. Relief of pain after sphin teroplasty was complete in 10 patients during foll up. Despite the problems in interpreting the morphine prostigmine test, the authors believe that the combined use of this test and ERCP in patients with indeterminate upper abdominal pain and suspected pancreatic disease is important and that a significant number of abnormalities of the sphincter of Oddi and the pancreatic duct are present in suc patients.

5775 CANCER OF THE PANCREAS IN BLACKS: A TEN YEAR EXPERIENCE. (Eng.)

Stevens, J.; Leffall, L. D., Jr.; Agbatha, A.; Anderson, J. (Howard Univ. Hosp., Washington, DC 20060). *J. Natl. Med. Assoc.* 69(4):249-251; 1977.

PANCREAS

Pancreatitis

5786 PANCREATITIS IN CHILDREN AND ADOLESCENTS. (Eng.) Jordan, S. C.; Ament, M. E. (Sch. Medicine, Univ. California, Los Angeles, CA 90024). *J. Pediatr.* 91(2):211-216; 1977.

Studies were carried out to establish normal serum values for amylase in children, to review the etiology of pancreatitis in children, and to characterize the clinical manifestations of pancreatitis in childhood. Normal serum amylase values (47.7 ± 28.6 mg/dl) were established for the pediatric age group in 68 subjects aged 0-17 yr; these values were higher than previously stated. Average serum amylase values increased with increasing age (r=0.55). The three commonest causes of pancreatitis in 54 patients studied were drug-induced (16), idiopathic (10), and traumatic (7). Prednisone was the most frequently implicated drug. Midepigastric pain and vomiting were the presenting symptoms in 75% of the patients. Serum amylase values were more than three times normal in 63.8% of patients; 17% of patients presented with normal serum amylase values. The typical patient received i.v. therapy for 5.4 days and was hospitalized for 9.4 days. Treatment with antibiotic and anticholinergic drugs did not alter mortality or morbidity rates. The mortality rate for acute interstitial pancreatitis was 17.5%, and for acute hemorrhagic pancreatitis, 86%.

5787 PHENFORMIN-ASSOCIATED PANCREATITIS. (Eng.)

Chase, H. S., Jr.; Mogan, G. R. (Mount Sinai Hosp., 100 St. and Fifth Ave., New York, NY 10029). *Ann. Intern. Med.* 87(3):314-315; 1977.

The case of a 70-yr-old diabetic man who developed acute hemorrhagic pancreatitis and severe lactic acidosis while taking phenformin is reported. The patient was not receiving any other medications, nor did he have any of the known metabolic conditions associated with pancreatitis. Four previously published cases of patients who developed acute pancreatitis while taking phenformin are reviewed. Three of those patients also developed lactic acidosis, a well-known complication of phenformin therapy. Although phenformin has been reported to increase the serum amylase activity and to alter the content of the pancreatic secretions in response to various stimuli, the manner in which the drug might cause acute pancreatitis remains completely unknown.

5788 AMYLASE ACTIVITY OF PAROTID SALIVA IN ACUTE AND CHRONIC PANCREATITIS. (Eng.)

Grimmel, K.; Rossbach, G.; Kasper, H. (Medizinische Universitatsklinik, Josef-Schneider-Str. 2, 8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(5):334-344; 1976.

Amylase activity was determined in the parotid saliva of patients with acute and chronic pancreatitis. In 17 patients with chronic relapsing pancreatitis between attacks, the mean amylase concentration (43.5 ± 32.5 U/ml) was significantly lower ($p<0.001$) than that of 17 control subjects (178.2 ± 84.5 U/ml) without pancreatic disease. Four patients with acute pancreatitis exhibited salivary amylase concentrations in the upper normal to grossly supranormal range (199.4-712.7 U/ml), whereas three patients with acute attacks of chronic relapsing pancreatitis showed reduced levels of amylase (17.3-60.7 U/ml) in comparison with controls and patients with acute pancreatitis. Unlike amylase output, the amylase concentration in the parotid resting saliva was independent of the salivary flow rate. The simultaneous infusion of secretin and pancreozymin produced a significant increase in the parotid salivary amylase levels in both patients without pancreatic disease and in those with chronic relapsing pancreatitis between acute attacks, with the post-treatment amylase concentrations being 251 ± 89.6 and 85.8 ± 61.2 U/ml, resp. Maximal stimulation of amylase following the infusion of the two hormones at 48 U/hr each was attained after a lag period of 15-30 min, irrespective of body weight. Since the amylase concentration, unlike amylase output, is independent of the parotid flow rate, the results indicate that the determination of amylase concentration in resting saliva is adequate for diagnosing pancreatic disease.

5789 SERUM IONIZED CALCIUM IN ACUTE PANCREATITIS. (Eng.)

Allam, B. F.; Imrie, C. W. (Stobhill General Hosp., Glasgow, G21 3UW, Scotland). *Br. J. Surg.* 64(9):665-668; 1977.

Serum ionized calcium was measured daily for 7 da after admission in eight consecutive patients wit acute pancreatitis to determine the frequency and degree of hypocalcemia. The results supported findings of the authors' previous study that the most common cause of the low serum calcium often found in pancreatitis patients is a low serum albumin; when correction of serum calcium is made for hypoalbuminemia, most patients are found to have normal calcium levels. The occasional hypocalcemia as shown by the "corrected" serum calciu or by serum ionized calcium measurement was usual mild and transient, indicating that the normal homeostatic mechanisms of the body efficiently maintained the physiologically active fraction of serum calcium within, or close to, the normal ran These findings explained the rarity of overt and subclinical tetany in acute pancreatitis and show that correction of serum calcium for albumin prov similar information to the direct measurement of serum ionized calcium. The value of "apparent" hypocalcemia in assessing severity of acute pancr atitis requires reappraisal, while greater attent should be directed towards the study and manageme of hypoalbuminemia in this disease.

5790 REACTIVE DUODENAL CHANGES IN CHRONIC PANCREATITIS SIMULATING THE CONTIGUOUS SPREAD OF PANCREATIC CARCINOMA. (Eng.)

Blacksto M. O.; Mizuno, H. (Dept. Medicine, Univ. Chicago, Box 400, 950 E. 59 St., Chicago, IL 60637). *Am. Dig. Dis* 22(7):658-661; 1977.

A case of chronic pancreatitis in which reactive changes of the duodenal mucosa simulated the contiguous spread of carcinoma and also predispos to a rare complication of endoscopic retrograde cholangiopancreatography (ERCP) is presented. Th patient, a 59-yr-old man with a 10-yr history of heavy drinking, presented with weight loss, anore early satiety, cramping abdominal pain, and nause and vomiting. An upper gastrointestinal series was interpreted as showing marked widening of the "C" loop with compression and irregularity of the loop, suggesting impingement on the duodenum by a mass in the head of the pancreas. Calcificatio within the head of the pancreas were also noted, and the picture was thought to represent carcinom of the head of the pancreas in preexisting chroni pancreatitis. Pancreatic ultrasound examination also suggested carcinoma. Examination of the duodenum during ERCP revealed an injected nodular, friable mucosa, although biopsies were negative for malignancy. ERCP was complicated by submucos injection of contrast material into the friable duodenal mucosa, which resulted in a portal venog The procedure was terminated, and the patient did not develop sepsis. Surgical exploration reveale severe chronic calcific pancreatitis with pseudocysts. A Whipple procedure was performed; carefu sectioning of the resected specimen did not demonstrate evidence of a tumor. This case illustrates the nonspecific nature of endoscopic and x-ray findings of the descending duodenum in pancreatic disease. The presence of marked mucos friability may be a relative contraindication to performing ERCP.

5791 COLONIC FISTULAS DURING ACUTE PANCREATITIS. REPORT OF THREE CASES. (Fre.) Giuli, R.; Colletas, J.; Lortat-Jacob, J. L. (Hopital Beaujon, 100, boulevard du General Leclerc, 92110 Clichy, France). *Ann. Chir.* 31(6):501-504; 1977.

A report of colonic fistula occurring late in the course of acute pancreatitis in 3 of 160 cases seen over a 10-yr period is presented. Two patients developed external fistulas 3 and 8 days, resp., after installation of an external drain; one succumbed to a massive hemorrhage, the other recovered fully. A third patient developed an internal fistula 1 month after evacuation of a false cyst. It healed spontaneously over the next two months. In view of the severe complications, mainly hemorrhage and infection, which usually follow fistulization and lead to a mortality rate of nearly 50%, surgical intervention to resect the affected colon segment is recommended.

5792 REVERSIBLE CRESCENTIC GLOMERULONEPHRITIS FOLLOWING AN ACUTE EXACERBATION OF CHRONIC RELAPSING PANCREATITIS. (Eng.) Dickmeyer, J. P.; Wolfson, W.; Kowell, A.; Dornfeld, L. (20426 Lake Chabot Rd., Suite 11, Castro Valley, CA 94546). *Arch. Intern. Med.* 137(8):1065-1067; 1977.

The case of a 42-yr-old man with recurrent episodes of acute glomerulonephritis following exacerbations of chronic relapsing pancreatitis is presented. Light microscopy of the renal biopsy performed during the episode of acute glomerulonephritis showed fibroepithelial crescents involving 70% of the glomeruli. The patient recovered without specific therapy. The time interval involved and the presence of subendothelial deposits with mesangial deposition of C3 complement and IgM suggest immune complex injury.

5793 CAUSES AND TREATMENT OF JAUNDICE ASSOCIATED WITH INFLAMMATORY PANCREATIC DISEASE. (Ger.) Neher, M.; Mangold, G.; Kummerle, F. (Chirurgische Universitatsklinik, 6500 Mainz, Langenbeckstr. 1, W. Germany). *Dtsch. Med. Wochenschr.* 102:644-647; 1977.

Biliary stasis or jaundice developed in 32 of 82 patients with acute pancreatitis and in 58 of 152 patients with chronic pancreatitis within 5 yr of treatment. Of these patients, a biliary cause was present in 12 with acute and 19 with chronic pancreatitis. Twenty-two of the 32 patients with acute pancreatitis had a hemorrhagic necrotizing course; 1 patient had an abscess of the pancreas. On the other hand, of 50 patients with acute pancreatitis but without jaundice, necrotic inflammations were only seen on 3 occasions. Clinical-chemical examination of patients with acute pancreatitis revealed obstructive jaundice with bilirubin levels up to 50 mg/l as compared to bilirubin levels of 50-150 mg/l in patients with chronic pancreatitis. The main form of therapy for biliary acute pancreatitis consisted of cleansing of the bile ducts by cholecystectomy, cholecystectomy with choledochus revision and a T-drain, sequestrotomy, and a left resection. Patients with biliary chronic pancreatitis with jaundice were subjected to similar measures in addition to partial or total duodenopancreatectomy, subtotal left resection (child), cystojejunostomy, and compensation of a biliodigestive anastomosis. Twenty-five of 38 patients with nonbiliary chronic pancreatitis had a resection of the pancreas head for severe inflammatory changes.

5794 CALCULOUS PANCREATITIS. (Rus.) Orlov, V. A. (I. M. Sechenov First Medical Inst., Moscow, USSR). *Klin. Med.* 55(4):81-83; 1977.

LIVER AND BILIARY TRACT

5795 LIVER SIZE IN NORMAL INFANTS AND CHILDREN. (Eng.) Carpentieri, U.; Gustavson, L. P.; Leach, T. M.; Bunce, H., III. (Univ. Texas Medical Branch, Galveston, TX 77550). *South. Med. J.* 70 9):1096-1097; 1977.

Liver span was determined in 165 healthy children 35 boys, 80 girls) between 2 months and 5 yr of age. The heights and weights of all children fell between the 5th and 95th percentiles for their age. The superior edge of the liver was delimited by percussion, while palpation was used for the inferior edge. Liver span was correlated significantly with body height, weight, surface area, and age. However, it was best correlated with body surface area (r=0.73), reflecting a constant relation between body size and liver size. Assessment of liver span is a useful test for evaluation of a child with apparent liver enlargement.

5796 LIVER DISEASE IN PREGNANCY.

(Ita.) D'Amato, T. (Ospedale Generale Provinciale di Venezia-Mestre, Divisione Osterica-Ginecologica, Venezia, Italy). *Minerva Ginecol.* 29(2):79-90; 1977.

Liver diseases that occur during and as a result of pregnancy are discussed. Special emphasis is placed upon the effect of idiopathic cholestatic icterus. A comparison was made of enzyme levels in the blood and amniotic fluid of 12 women with icterus and 14 healthy women. The enzymes studied included SGPT, SGOT, lactic dehydrogenase, cholinesterase, leucine aminopeptidase, and alkaline phosphatase. No significant difference was found in enzyme levels in the two groups, suggesting that such measurements are not good indications of fetal stress during pregnancy. It is recommended that, in a clinical situation, fetal distress be determined by other means. Other liver diseases, particularly viral hepatitis, are discussed in light of recent literature.

5797 LIVER TISSUE LECITHIN: CHOLESTEROL ACYLTRANSFERASE ACTIVITY IN PATIENTS WITH LIVER DISEASE.

(Eng.) Ras, M. R.; Frison, J. C.; Rubies-Prat, J.; Romero, R.; Masdeu, S.; Schwartz, S. (Dept. Internal Medicine, Ciudad Sanitaria de la Seguridad Social, Universidad Autonoma, Av. Valle Hebron s/n, Barcelona 16, Spain). *Biomedicine* 27 (4):141-143; 1977.

To study the relation between cholesterol acyltransferase (LCAT) and related lipid disturbances in blood and liver biopsies, LCAT activity was determined in the sera and liver tissue of 21 patients with parenchymal liver disease and in 5 healthy controls. Serum LCAT activity was normal in the 21 patients with liver damage (25.4 ± 5.5 μg/ml/hr), the level being similar to that in controls (23.7 ± 2.8 μg/ml/hr). A good correlation was found between serum LCAT activity and the proportion of serum cholesterol esters ($r=0.57$, $p<0.01$). The proportion of esterified cholesterol in liver biopsy specimens in the patients was similar to that in controls and was relatively low compared with those in serum (33.6 ± 10.2% versus 69.7 ± 5.1%, $p<0.001$). No correlation was found between the relative proportion of phospholipids and other lipid fractions, neither in serum nor in liver tissue. The proportion of cholesterol esters in liver tissue is much higher than expected according to the low tissue LCAT activity; this suggests that cholesterol esters in parenchyma may be a storage form of cholesterol esterified in plasma pool.

5798 TYRAMINE OXIDASE ACTIVITY IN NEEDLE BIOPSY OF NORMAL LIVERS AND DISEASED LIVERS.

(Eng.) Arima, T.; Okada, Y.; Kubota, M.; Nagata, K.; Higuchi, Y.; Hayashi, S.; *et al.* (Okayama Univ. Medical Sch., 2-5-1, Shikata-Cho, Okayama 700, Japan). *Enzyme* 22(2):124-129; 1977.

The activities of tyramine oxidase (TO), UDP-glucuronyl transferase (GT), and acetyl CoA (AC) in needle biopsies of abnormal livers from 42 patients were determined and compared with those of 10 normal specimens. The TO, GT, and AC activities (U/kg protein) of normal livers ranged from 2,610 to 3,54 734 to 1,025, and 21.1 to 26.6, resp. The TO, GT, and CA activities of the abnormal specimens were: 1,960-4,650, 604-898, and 20.3-28.2, resp., for 15 patients with active chronic hepatitis; 3,970-4,160 660-678, and no data (nd), resp., for 2 patients with fatty liver (unknown cause); 3,200-3,330, 615-886, and 46.5-64.6, resp., for 2 patients with alcoholic fatty liver; 3,670-4,520, 723-732, and nd, resp., for 2 patients with toxic hepatitis; 3,290-3,510, 726-943, and nd, resp., for 2 patients with inactive chronic hepatitis; 2,130, 809, and nd resp., for 1 patient with acute hepatitis in convalescence; 2,320-2,810, 745-828, and 38.2, resp., for 2 patients with alcoholic fibrosis; 1,820-2,400 923-959, and 22.5, resp., for 3 patients with alcoholic hepatitis; 760-2,250, 507-807, and 1.71, resp., for 2 patients with active alcoholic cirrhos 2,730-3,540, 756-859, and nd, resp., for 2 patients with inactive alcoholic cirrhosis; 2,580-3,140, 700 831, and 22.6, resp., for 2 patients with active nonalcoholic cirrhosis; 2,990, 801, and nd, resp., for 1 patient with Banti's syndrome; 4,090, 608, and nd, resp., for 1 patient with primary biliary cirrhosis; 3,550, 541, and nd, resp., for 1 patient with Gilbert's disease; 2,920, 868, and nd, resp., for 1 patient with Rotor's disease; 2,470, 658, and 18.4, resp., for 1 patient with intrahepatic cholestasis; 3,180, 923, and 18.5, resp., for 1 patient with cholangiohepatitis; and 1,690, 571, and 40.7, resp., for 1 patient with acute cardiac venous stasis. Thus, TO was elevated in livers with nonalcoholic fatty change or toxic hepatitis and reduced in livers with fibrosis or chronic alcoholic injury. GT activity was reduced in livers with severe parenchymal damage or hyperbilirubinemia. AC activity was decreased markedly in active alcoholic cirrhotic liver and was elevated in alcoholi fatty livers as well as in a liver with acute veno stasis.

5799 TRANSJUGULAR LIVER BIOPSY.

(Eng.) Gilmore, I. T.; Bradley, R. D.; Thompson, R. P. H. (St. Thomas' Hosp., London SE1 7EH, England). *Br. Med. J.* 2(6079):100-101; 1977.

Experience with taking liver biopsy specimens thro a hepatic vein, entering from the right internal jugular vein, was assessed in 26 patients. Biopsy specimens were obtained in all 26 patients but wer adequate for full histological assessment only in 16. No patient showed any sign of blood loss afte the procedure. Transjugular liver biopsy is valuable when percutaneous biopsy is hazardous, or whe pressure measurements or venography are also required.

5800 'ROUTINE' LIVER BIOPSY IN UPPER ABDOMINAL SURGERY. (Eng.) Michel, S. L.; Lipsky, R.; Morgenstern, L. (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *Arch. Surg.* 112(8):959-961; 1977.

The incidence of unsuspected or undiagnosed hepatic abnormalities was assessed in 125 patients in whom a liver biopsy was carried out routinely at the time of elective or emergency abdominal surgery. Specifically excluded were hepatic lesions unexpectedly identified at laparotomy. Sixty-seven percent of the liver biopsy specimens were abnormal, the most frequent findings being fatty metamorphosis, cholestasis, triaditis, fibrosis, inflammatory infiltrate, cholangitis, cirrhosis, and hepatitis. The most frequent operation performed was cholecystectomy. In 63 patients with chronic cholecystitis, there was a 51% incidence of abnormal liver histology, while in 9 patients with acute cholecystitis, the incidence was 78%. In 83% of all other operations, abnormal liver biopsy specimens were identified. Bile leakage, hemorrhage, and infection did not occur in this series, despite inclusion of patients with severe biliary obstruction, abnormal clotting factors, and intra-abdominal sepsis. New techniques of histochemical enzyme analysis and electron microscopy are expected to enhance the clinical correlation of occult hepatic lesions. Liver biopsy is a safe, informative adjunct to all upper abdominal procedures.

5801 CORRELATION OF COMPUTED TOMOGRAPHY, GRAY SCALE ULTRASONOGRAPHY, AND RADIONUCLIDE IMAGING OF THE LIVER IN DETECTING SPACE-OCCUPYING PROCESSES. (Eng.) Bryan, P. J.; Dinn, W. M.; Grossman, Z. D.; Wistow, B. W.; McAfee, J. G.; *et al.* (Upstate Medical Center, 750 E. Adams St., Syracuse, NY 13210). *Radiology* 124(2):387-393; 1977.

Experience with the use of computed tomography (CT; scanning time=2.7 min), gray scale ultrasonography, and radionuclide imaging in 51 patients with space-occupying hepatic lesions is reviewed. The abilities of the three modalities to detect these lesions were graded on a numerical rating scale from 0 to 5. Ultrasonography scored 3.5, CT scored 3.2, and radionuclide imaging scored 2.9. CT resulted in no false-positives and six false-negatives (12%), caused mainly by motion artifacts. The simplest technique, radionuclide imaging, also had the smallest number of false-negatives (2 cases or 4%) and is, therefore, recommended as the screening procedure of choice. The false-positive rate for this procedure was 4%. The false-positive rate for sonography was 2%, and the false-negative rate was 6%. Sonography or CT should be carried out in patients with prior suspicious findings.

5802 WOUND HEALING AND COMPLICATIONS OF THE LIVER AFTER PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. (Eng.) Mori, W.; Mukawa, K. (Univ. Tokyo Faculty Medicine, 7-3-1 Hongo, Bunkyo-ku, Tokyo, 113 Japan). *Acta Hepatogastroenterol. (Stuttg.)* 24(2):86-92; 1977.

Hepatic damage and wound healing were examined at autopsy in 10 patients who had received percutaneous transhepatic cholangiography (PTC). Autopsies were performed day 0, 2, 7, 13, 16, 41, 42, 53, and 56 after PTC examination. The diagnosis had been pancreas head carcinoma in three cases; gallbladder carcinoma in two cases; hepatic duct carcinoma in one case; bile duct carcinoma in one case; intrahepatic bile stasis in one case; hemolytic anemia, cholelithiasis, and liver cirrhosis in one case; and Paget's disease with obstructive jaundice due to metastasis in one case. Hemocoagulation or hematoma formation on the hepatic surface and intraperitoneal hemorrhage were seen at the 7th day after PTC, but not on the 13th day. The puncture scar on the hepatic capsule was seen up to the 16th day after PTC, but not on the 41st day or thereafter. Damage to the hepatic parenchyma was observed until the 7th day after PTC and was repaired by the 13th day. Intrahepatic hematoma was seen until the 13th day after PTC. In general, intrahepatic trauma caused by PTC appeared to be completely absent, without evidence of scar, after about 2 weeks.

5803 BILIARY COMPLICATIONS AFTER LIVER TRANSPLANTATION: WITH SPECIAL REFERENCE TO THE BILIARY CAST SYNDROME AND TECHNIQUES OF SECONDARY DUCT REPAIR. (Eng.) Starzl, T. E.; Putnam, C. W.; Hansbrough, J. F.; Porter, K. A.; Reid, H. A. S. (Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO 80220). *Surgery* 81(2):212-221; 1977.

Biliary complications after liver transplantation are discussed with special reference to biliary cast syndrome. In 93 consecutive cases of orthotopic liver transplantation, there were 24 cases of biliary obstruction and 8 of bile fistula formation. Six of the obstructed livers developed biliary cast formation, which was so extensive that the smaller intrahepatic ducts became plugged to an extent that they could no longer be treated surgically. Bile duct reconstruction in these six patients had been by cholecystoduodenostomy in five patients and choledochocholedochostomy in the sixth. In each of the six cases, the most important causative factor was neglected obstruction of the large bile ducts, with the intrahepatic lesions apparently being late and secondary. Stone and/or cast formation also occurred in other obstructed livers in the presence of bile fistulas, but these deposits were limited to the large ducts where they could be removed. Although homograft bile undoubtedly increased lithogenicity at certain postoperative times, biliary sludge formation was always associated with defective bile duct reconstruction, underscoring the urgency with which reoperation must be considered. Secondary intervention involving the conversion from cholecystojejunostomy to choledochojejunostomy resulted in the salvage of homografts in eight of nine patients and in the survival of seven of these patients. When the original reconstruction was with cholecystoduodenostomy, a procedure which was abandoned because of its poor results, the secondary operation was to anastomose the dilated common duct to the defect in the duodenum. Only one survivor emerged from six such attempts, and this survivor eventually required conversion to Roux-en-Y choledochojejunostomy because of repeated bouts of cholangitis. The other five patients died from regional and systemic infection, duodenal fistula, and inadequate biliary decompression.

5804 TRANSPLANTATION OF THE LIVER. (Eng.)

Putnam, C. W.; Starzl, T. E. (Univ. Colorado Medical Center, 4200 East Ninth Ave., Denver, CO 80262). *Surg. Clin. North Am.* 57(2):361-373; 1977.

Experience with 113 cases of liver transplantation is presented. Of 103 patients undergoing transplants more than 1 yr ago, 30 are still alive. Transplants have been performed for nonresectable hepatoma, cholangiocarcinoma, hemangioendothelial sarcoma, Klatskin tumor, biliary atresia, alcoholic cirrhosis, postnecrotic cirrhosis, chronic aggressive hepatitis, Wilson's disease, α_1-antitrypsin deficiency, primary biliary cirrhosis, and the Budd-Chiari syndrome. Successful transplantation has not yet been achieved for patients with fulminant liver failure from hepatitis or other toxic agents. The worst results have been in patients with alcoholic cirrhosis; of 10 alcoholics transplanted, only one has achieved long-term survival. In contrast, patients with postnecrotic cirrhosis or chronic aggressive hepatitis have a much more favorable prognosis. The validity of metabolic correction by liver transplantation was established in a 16-yr-old girl with α_1-antitrypsin deficiency. After a first transplant, which was eventually rejected, the patient developed normal levels of α_1-antitrypsin and adopted the donor phenotype. Following a retransplantation after rejection of the initial graft, the patient died of pulmonary infectious complications. With the exception of reestablishing biliary drainage, the technical problems surrounding liver transplantation have largely been solved.

5805 ALPHA-1-ANTITRYPSIN DEFICIENCY. (Ger.)

Kunzer, W. (Univ.-Kinderklinik, Mathildenstr. 1, 7800 Freiburg i. Br., W. Germany). *Klin. Paediatr.* 189(3):199-205; 1977.

The relation of alpha-1-antitrypsin (AT) deficiency to specific diseases is reviewed. A deficiency of AT is associated with neonatal hepatitis, obstructive pulmonary emphysema, membrane proliferative glomerulonephritis, rheumatoid arthritis, Weber-Christian disease, myopathies, and ulcerative colitis. AT comprises about 90% of the alpha-1-globulins in the serum and is also found in small quantities in amniotic fluid, duodenal juice, bronchial and nasal secretions, saliva, tears, colostrum, and breast milk; its half-life is 5-6 days, and it is probably produced in the liver. Several genetic variants of AT exist due to the existence of multiple codominant alleles at a single locus. AT inhibits proteolytic enzymes. In homozygotes, the protease inhibitor (Pi) type MM is dominant, as compared wit Pi types MX and MS in heterozygotes. Newborns with Pi type ZZ are highly susceptible to disease, especially liver diseases, because this type causes serious AT deficiency. These liver diseases, whose pathogenesis is unclear, may be neonatal hepatitis, hepatomegaly, hepatosplenomegaly, or portal hypertension with hematemesis. In addition to liver cell inclusions, cholestasis, bile duct granulation infiltrated portal fields, giant cell formation, hematopoetic foci, cell necroses, portal firbosis, and cirrhosis have also been found in children with defective alleles and liver function disturbances. No successful therapy is known; phenobarbital and prednisone do not affect blood AT levels, nor do they prevent the development of cirrhosis. Prophylactic measures are required, and alcohol and nicotine use should be avoided.

5806 SERUM ANTIBODIES IN PATIENTS WITH EXTRAINTESTINAL AMEBIASIS (AMEBIC LIVER ABSCES AND HEALTHY PERSONS. (Ger.)

Mannweiler, E.; Mohr, W.; Hofler, W.; Lederer, I. (Bernhard-Nocht-Institu fur Schiffs- und Tropenkrankheiten, 2000 Hamburg 4, Bernhard-Nocht-Str. 74, W. Germany). *Dtsch. Med. Wochenschr.* 101(52):1915-1919; 1977.

Tests for serum antibodies against two ameba antigens were performed by complement fixation, indirect hemagglutination (IHA), latex agglutination (LA), and double gel diffusion on the sera of 70 patients with amebic liver abscesses, 204 travelers returning from tropical countries, and 136 inhabitants from a region of endemic amebiasis but without evidence of the disease. Suspicious or borderline results were noted in 73.3% of sera of patient with extraintestinal amebiasis by IHA and in 90.4% by LA. Of the sera from the 204 travelers, suspicious or borderline serum antibody tests against the two antigens were detected in 12.1% (IHA) to 18.9% (LA) of the samples as compared with 16.2% (LA) to 46.3% (IHA) of the samples from 136 inhabitants of the endemic disease region. The serum of one patient who died of multiple liver abscesses was negative in all immunological tests. Antibody titers could still be detected in one patient with amebic liver abscess up to 2 years after therapy. Overall, useful diagnostic results were obtained most frequently in patients with amebic liver abscess after several different tests had been performed.

5807 BUDD-CHIARI SYNDROME AFTER TAKING ORAL CONTRACEPTIVES: A CASE REPORT AND REVIEW OF 14 REPORTED CASES. (Eng.)

Wu, S. M.; Spurny, O. M.; Klotz, A. P. (Menorah Medical Cente 4949 Rockhill Rd., Kansas City, MO 64110). *Am. J. Dig. Dis.* 22(7):623-628; 1977.

The case of a patient who developed the Budd-Chiari syndrome after taking oral contraceptives is presented, and 14 similar cases in the literature are

eviewed. The patient, a 24-yr-old woman, had been
aking oral contraceptives (norethindrone acetate
nd ethinyl estradiol) for 4 yr. She presented with
ausea, anorexia, cramping abdominal pain, headache,
onstipation, and discolored urine. After discon-
inuing the contraceptives, her symptoms became more
ntense, and her abdomen was distended with ascites.
ne liver function tests were abnormal, and she had
sudden onset of tachycardia and stupor. Hepatic
ein thrombosis was diagnosed, on the basis of sel-
ctive hepatic arteriogram findings. Therapy with
nticoagulant was not initiated because of a low
brinogen level (107 mg/dl), a prolonged activated
rtial thromboplastin time (40/29 sec), and a pro-
nged prothrombin time (25/11.5 sec). Her fibrin
lit products were not present, and the platelet
unt was normal. Her mental status improved fol-
wing neomycin therapy. She developed thrombo-
lebitis, and low-dose therapy with heparin was
gun. A vena cavagram showed obstruction of the
patic vein and marked narrowing of the inferior
na cava and obstruction of the left iliac vein.
e improved after continued treatment with neomy-
n, heparin, and diuretics, and her liver function
sts (except for blood ammonia) returned to normal.
llow-up studies showed increasing abdominal venous
llateral circulation; moderately elevated liver
zymes; total occlusion of the inferior vena cava
th the development of collateral circulation;
ophageal varices; and hepatic, portal, and splenic
in occlusion.

08 DIFFERENTIAL DIAGNOSIS OF BENIGN LIVER TUMORS.

(Ita.) Mangold, G.;
rschner, P.; Wagner, R.; Hohn, P. (Chirur-
sche Universitatklinik, Universitat Mainz, 65
inz, Langenbeckstr. 1, W. Germany). *Minerva*
d. 66(63):3261-3267; 1975.

o patients with focal nodular hyperplasia were
eated with surgical intervention. Although the
esenting symptoms of both patients were not
aracteristic of liver neoplasms, angiogram exam-
ation revealed the presence of a vascularized
ver tumor. Histologically the tumors appeared
be hamartomas. Definitive classification was
fficult, however, because of confusion in the
erature about the classification of benign liver
nors. The symptoms, diagnosis, therapy, and
stology of benign liver tumors are briefly dis-
sed.

09 57-COBALT-BLEOMYCIN AS A TUMOR SCANNING AGENT IN PRIMARY HEPATOCELLULAR CANCER.

g.) Kew, M.; Allen, J.; Levin, J. (Johannesburg
eral Hosp., Johannesburg, S. Africa). *Eur. J.*
l. Med. 1(4):247-250; 1976.

o-bleomycin and ^{99m}Tc-sulfur colloid scans were
formed in 13 southern African Negro patients with
mary hepatocellular cancer (PHC) and 3 patients
h other space-occupying hepatic lesions. Visual
parisons of scan pictures from bleomycin and sul-
colloid scans were used to assess uptake ability.
ective concentration of ^{57}Co-bleomycin in the defects seen on the ^{99m}Tc-sulfur colloid scan occurred in only 4 of the 13 patients with PHC. The ^{57}Co-bleomycin and ^{99m}Tc-sulfur colloid scans were identical to the remaining PHC patients, as well as in the two patients with metastatic liver disease and the one patient with an amebic liver abscess. It appears that ^{57}Co-bleomycin has only a limited place as a tumor-seeking agent in the diagnosis of PHC in southern African Negroes.

5810 DIAGNOSIS OF HEPATOCELLULAR CARCINOMA BY SERIAL DETERMINATION OF SERUM α-FETOPROTEIN CONCENTRATION.

(Jpn.) Yumoto, Y.; Namba, T.; Tanaka, Y.; Taketa, K.; Ohta, Y.; Mitani, K. (Okayama Univ. Medical Sch., Okayama, Japan). *Jpn. J. Gastroenterol.* 73(6):659-667; 1976.

The clinical significance of serum alpha fetoprotein (AFP) determination by radioimmunoassay (RIA) in the diagnosis of hepatocellular carcinoma was studied. The mean serum AFT value in 30 healthy controls was 5.6 ± 2.6 ng/ml. Normal horse serum was used to dilute the sera of patients with high AFP levels. The level of serum AFP was over 2,000 ng/ml in 75.5% of 49 patients with hepatocellular carcinoma, in 0.64% of 157 patients with hepatitis or liver cirrhosis, and 3.8% of 52 patients with gastric cancer metastatic to the liver. Histological examination of tissue from four patients with hepatocellular carcinoma in whom the serum AFP level remained below 300 ng/ml revealed only stages I and II carcinoma; stage III carcinoma occurred only in patients with AFP levels over 300 ng/ml.

5811 ANGIOGRAPHIC DEMONSTRATION OF INTRAHEPATIC ARTERIO-PORTAL ANASTOMOSES IN HEPATOCELLULAR CARCINOMA.

(Eng.) Okuda, K.; Musha, H.; Yamasaki, T.; Jinnouchi, S.; Nagasaki, Y.; Kubo, Y.; *et al.* (Chiba Univ. Hosp., Chiba 280, Japan). *Radiology* 122(1):53-58; 1977.

Hepatic angiograms of 114 patients with hepatocellular carcinoma (HCC) were studied to investigate intrahepatic arterioportal anastomoses. Arterioportal shunts of varying sizes, evidenced by opacification (contrast medium, 30-50 ml of 70% sodium methylglucamine diatrizoate) of intrahepatic portal branches, were seen in 72 patients. Retrograde flow of the contrast medium beyond the hilus and back into the portal vein was reported in 29 cases. The flow of contrast medium was antegrade when normal portal branches were opacified. Maximum frequency of opacification was reported in the portal vein (21%) and its smaller branches (22.18%). Four types of shunts were found: (1) through a tumor thrombus in the portal branch, (2) in a retrograde direction via a peripheral tumor nodule, (3) through a small tumor invading or amputating an artery, and (4) through a tumor located near a major portal vein branch and supplied by a large, coiling artery. This last type is very rare (5 cases). The exact course of contrast medium transit could be delineated only in this type. Postmortem angiography of the liver (with ultrafine barium sulfate) in 50 patients with HCC suggests that arterioportal shunts are the result of the special vasculature in HCC and are highly diagnostic when accompanied by other angiographic changes.

5812 CLINICOPATHOLOGICAL STUDIES OF MINUTE HEPATOCELLULAR CARCINOMA. ANALYSIS OF 20 CASES, INCLUDING 4 WITH HEPATIC RESECTION.

(Eng.) Okuda, K.; Nakashima, T.; Obata, H.; Kubo, Y. (Chiba Univ. Hosp., Chiba 280, Japan). *Gastroenterology* 73(1):109-115; 1977.

Liver specimens of sixteen autopsies and four cases of hepatic resection in which the liver had a solitary hepatocellular carcinoma smaller than 4.5 cm, or a few tumor nodules smaller than 3.5 cm, were analyzed. Clinically, these patients presented with signs and symptoms compatible with cirrhosis (spider nevi, stigmata of portal hypertension, low SGOT:SGPT ratio). Of the 16 autopsy cases, only 2 had been diagnosed correctly. In all but four cases, the noncancerous parenchyma showed advanced cirrhosis of the mixed type, with irregularly sized multilobular nodules and thin strands of stroma, different from typical alcoholic cirrhosis. The primary lesion was grossly encapsulated in the majority, suggesting a slow, expanding growth. Histologically, most primaries were relatively well differentiated. Serum α-fetoprotein was generally low (<100 ng/ml in 7 patients, 100-1,000 ng/ml in 3, and >1,000 ng/ml in 4), and it served as the major diagnostic clue in only five cases. In patients with mildly abnormal α-fetoprotein levels, continuous monitoring seems important to detect a steady rise, the first warning for tumor growth.

5813 RADIOTHERAPY OF HEMANGIOMA CAVERNOSUM OF THE LIVER.

(Eng.) Okazaki, N.; Yoshino, M.; Yoshida, T.; Ohno, T.; Kitagawa, T.; Hattori, N. (Natl. Cancer Center Hosp., Tsukiji 5-1-1, Chuo-ku, Tokyo, Japan 104). *Gastroenterology* 73(2): 353-356; 1977.

Experience with radiotherapy in four patients with massive cavernous hemangioma of the liver is presented. Each patient received 6 MeV x-ray, and favorable results were obtained in three. The tumor in the remaining patient, a 41-yr-old man in whom an abdominal mass had been untreated for 5 yr, showed no response to a total tumor dose of 940 rads; the patient died 6 months later. Patient 2, a 39-yr-old woman, received a total dose of 1,900 rads over 54 days, with a daily dose of 50-100 rads. Although the hemangioma regressed after treatment, the response was transient. A total tumor dose of 2,940 rads was given over 41 days, with a daily dose of 100-200 rads as a second course, and the hemangioma regressed with no sign of re-enlargement. Patients 3 and 4 were given 150-200 rads every other day to a total of about 3,000 rads, with satisfactory regression of both tumors. Follow-up studies showed that patients 2-4 were well 8, 5, and 4 yr after radiotherapy, resp. Because a total tumor dose of 3,000 rads is sufficient to produce permanent histological kidney damage or "radiation hepatitis," a somewhat smaller total dose with a sufficient fractional dose is advisable (although no such changes occurred in these patients).

5814 KUPFFER CELL SARCOMA OF THE LIVER: REPO
OF 2 CASES IN SOUTH AFRICAN BLACKS. (En

Greenberg, M. (Baragwanath Hosp., Johannesburg,
South Africa). *S. Afr. Med. J.* 52(6):244-246; 19

The first known cases of Kupffer cell sarcoma of t
liver in two South African black patients are re-
ported. The first patient, a 26-yr-old woman, die
3 months after developing abdominal pain. The sec
ond patient, a 56-yr-old man, presented with an
acute abdomen and died after laparotomy 6 days lat
Neither patient was jaundiced. Autopsy revealed
an enlarged, nodular, hemorrhagic liver with areas
of necrosis in both cases. The normal architectu
was almost completely destroyed by a diffusely in-
filtrating vascular malignancy. Large lacunae an
anastomosing channels were apparent. The neoplas
cells lining these spaces ranged from small elong-
ated or spindle-shaped, to larger more pleomorphi
and bizarre cells. Multinucleate giant cells wer
also seen. Mitoses were rare in the first patien
but were more frequent in the second. The neopla
endothelial cells in the second patient tended to
be larger and more bizarre, and hemopoietic foci
were prominent. No evidence of cirrhosis or expo-
sure to Thorotrast was present in either patient.

5815 REVIEW: ENDOTOXINS AND LIVER DISEASE.

(Eng.) Wilkinson, S. P. (King's Coll.
Hosp., Denmark Hill, London, S.E.5, England). *Sc*
J. Gastroenterol. 12(4):385-386; 1977.

The role of endotoxins in liver diseases and poss
methods for treating endotoxemia are reviewed. I
terest in the role of endotoxins in liver disease
is twofold. First, endotoxins are hepatotoxic an
might therefore directly contribute towards the
pathogenesis of some forms of liver disease. Sec
ond, with the development of a portasystemic coll
teral circulation, endotoxins are likely to esca
into the systemic circulation and might be respo
sible for some extrahepatic manifestations of
liver disease, such as renal failure and intrava
cular coagulation. Liver necrosis, occurring se
ondary to an experimental choline-deficient diet
can be prevented or delayed if the experimental
animals are either raised in a germ-free environ-
ment or given p.o. nonabsorbable antibiotics. T
severity of galactosamine hepatitis can be dimin
by prior colectomy. These and other studies sug
that the products of intestinal bacteria are at
least partly responsible for the development of
injury. A role for endotoxins is particularly
likely in alcoholic liver disease. Systemically
administered endotoxins have caused renal failur
intravascular coagulation, and gastric mucosal h
orrhage in experimental animals, which may provi
an explanation for the close correlation between

systemic endotoxemia and the development of these complications in patients with fulminant hepatic failure. Possible treatments for endotoxemia include immunization, nonabsorbable antibiotics (e.g., neomycin), and polymyxins.

5816 TREATMENT OF FULMINANT HEPATIC FAILURE BY POLYACRYLONITRILE-MEMBRANE HAEMODIALYSIS. (Eng.) Silk, D. B. A.; Trewby, P. N.; Chase, R. A.; Mellon, P. J.; Hanid, M. A.; Davies, M.; *et al.* (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5, England). *Lancet* 2(8027):1-3; 1977.

The value of hemodialysis with a polyacrylonitrile membrane was studied in 24 patients with fulminant hepatic failure who had deteriorated to grade IV coma. Nine of the 24 treated patients fully recovered consciousness, and eight survived to leave the hospital. These results are compared with previously reported results in patients receiving conservative management alone (15% survival in 53 cases) and those obtained initially with charcoal hemoperfusion (38%). Of the 16 treatment failures, cerebral edema was found at necropsy in 13. Whether this would have been less of a problem if treatment had been started earlier in the course of the illness remains to be determined.

5817 TREATMENT OF GAUCHER'S DISEASE WITH LIPOSOME-ENTRAPPED GLUCOCEREBROSIDE: β-GLUCOSIDASE. (Eng.) Belchetz, P. E.; Crawley, J. C. W.; Braidman, I. P.; Gregoriadis, G. (Sch. Medicine, Univ. Pittsburg, Pittsburg, PA 15261). *Lancet* 2 (8029):116-117; 1977.

The treatment of Gaucher's disease with liposome-entrapped glucocerebroside:β-glucosidase is reported. The patient, a 25-yr-old woman, received 10 ml of a mixture of liposomes containing 1,320 U of glucoerebroside:β-glucosidase and ^{111}In-labeled lipoomes (0.3 mCi) i.v. on March 15; entrapped enzyme was administered again on March 19 (1,876 U), June 9 (10,819 U), and October 20 (403 U). On December , she received ^{111}In-labeled liposomes (1.2 mCi) and on April 4, a fifth dose (260 U) of the entrapped nzyme was administered. After this treatment, the ower border of the right hepatic lobe had moved p 3 cm, and the left lobe had shrunk. Reduction n the size of the liver was associated with relief f pressure symptoms in the left lower abdomen. uring treatment, the plasma level of aspartic cid transaminase fell from 70 to 50 IU/l, glutamyl ranspeptidase ranged from 200 to 300 IU/l, and lkaline phosphatase fell from 45 to 35 King Armtrong U. Whole body scans showed an increased rate f elimination of liposomes from the circulation fter 9 months of treatment, reflecting improvement n the participation of liver in liposome uptake. he results suggest that liposomes hold promise n the treatment of Gaucher's disease.

818 END-TO-SIDE ANASTOMOSIS OF THE MESENTERIC VEIN TO THE INFERIOR VENA CAVA IN THE REATMENT OF GLYCOGEN STORAGE DISEASE: CASE REPORT. Eng.) Esato, K.; Yasutake, S.; Kaku, R.; Yamaki, R. (Yamaguchi Univ. Sch. Medicine, Ube, Yamaguchi, Japan). *Surgery* 82(2):287-290; 1977.

The case of a patient who underwent an end-to-side anastomosis of the mesenteric vein to the inferior vena cava for the treatment of Type I glycogen storage disease is presented. The patient was investigated at the age of 2 yr for hepatomegaly, at which time the liver was palpable 12 cm below the costal margin, and no ascites were present. At laparotomy, the mesenteric vein was cut near the junction of the ileocolic vein, 3 cm of its proximal segment was separated from the accompanying artery, and it was anastomosed to the inferior vena cava. The patient had an uneventful postoperative course, and the liver had become almost unpalpable by the fifth month after surgery. At this time, the previously elevated serum cholesterol and blood sugar levels had returned to normal. The blood ammonia level increased but remained within normal limits, and ketonuria had disappeared completely. Four years after surgery, the blood sugar and ammonia levels were still within normal limits, but the serum cholesterol was higher than normal. The serum alkaline phosphatase and SGPT levels decreased but did not return completely to normal. The patient was asymptomatic, and his height and weight were normal. The efficacy and simplicity of end-to-side anastomosis of the mesenteric vein to the inferior vena cava suggest that it should be used in further cases of glycogen storage disease.

5819 SELECTIVE HEPATIC ARTERY EMBOLIZATION TO CONTROL MASSIVE HEPATIC HEMORRHAGE AFTER TRAUMA. (Eng.) Rubin, B. E.; Katzen, B. T. (George Washington Univ. Medical Center, 901 23rd St., N.W., Washington, DC 20037). *Am. J. Roentgenol.* 129(2):253-256; 1977.

Two patients in whom angiography and transcatheter embolization techniques were used in the diagnosis and treatment of intrahepatic and intraperitoneal hemorrhage due to trauma are reported. Selective and subselective arteriography identified the hemorrhagic artery in each case. Transcatheter therapeutic embolization successfully stopped the hemorrhage acutely in one patient and produced almost complete cessation of hemorrhage in the other patient. No further blood replacement was required after the embolization procedures. Liver function tests were abnormal prior to embolization and gradually improved afterward. Neither patient required surgery, and both were discharged from the hospital. Each patient has remained free of symptoms for 5 and 4 months, resp. Arteriography offers accurate diagnostic information and therapeutic potential in patients who experience hemorrhage following trauma. In addition, therapeutic embolization may offer decreased morbidity and reduced hospital stay. Successful results of therapeutic embolization depend on awareness of its usefulness and upon rapid mobilization of angiographic and support personnel.

5820 THE HEPATIC PORPHYRIAS: PATHOGENESIS, MANIFESTATIONS, AND MANAGEMENT. (Eng.)

Bloomer, J. R. (Dept. Medicine, Yale Univ. Sch. Medicine, New Haven, CT). *Gastroenterology* 71(4): 689-701; 1976.

The pathogenesis, manifestations, and management of hepatic porphyrias are reviewed. The following types of hepatic porphyrias and their clinical and biochemical manifestations are identified: acute intermittent porphyria with neuropsychiatric symptoms (NS) and elevated urinary levels of prophobilinogen (PBG) and delta-aminolevulinic acid (ALA); variegate porphyria (VP), with skin lesions (SL), elevated urinary coproporphyrin (COP), PBG, and ALA, and elevated fecal levels of COP and protoporphyrin (PRO); hereditary coproporphyria (VP, SL, elevated urinary levels of COP, PBG, and ALA, and elevated fecal COP); porphyria cutanea tarda, with SL, structural hepatic disease (SHD), and elevated urinary uroporphyrin; protoporphyria (SL, SHD, elevated red cell PRO, and elevated fecal PRO); and secondary porphyrinuria (SHD and elevated urinary COP). All of the hepatic porphyrias are inherited in an autosomal dominant pattern, with the possible exception of porphyria cutanea tarda; however, clinical manifestations rarely develop before puberty, except in protoporphyria where there is usually life-long photosensitivity. Histologically, birefringent pigment deposits in the liver is a specific feature of protoporphyria because hepatic pigment deposits in various other disorders do not show birefringence. Cholelithiasis occurs in some patients with protoporphyria. Liver disease is common in patients with porphyria cutanea tarda, with hepatic siderosis being a common feature. In secondary porphyrinuria, an observed increased urinary excretion of coproporphyrin is presumable, due in large part to the fact that biliary excretion of this compound is impaired. Current therapy for hepatic porphyrin disorders includes chlorpromazine, propoxyphene, and glucose loading for mild attacks and glucose loading, meperidine, and hematin infusions for severe attacks of acute intermittent porphyria. Phlebotomy is used to manage porphyria cutanea tarda. In protoporphyria, skin manifestations are treated with β-carotene, and hepatic disease is treated with cholestyramine and sometimes, with vitamin E. Secondary porphyrinuria is managed by treating the underlying hepatobiliary disease.

5821 HEREDITARY HEPATIC PORPHYRIAS IN FINLAND.

(Eng.) Mustajoki, P.; Koskelo, P. (Third Dept. Medicine, Univ. Helsinki, Helsinki, Finland). *Acta Med. Scand.* 200(3):171-178; 1976.

The occurrence of hepatic porphyrias (acute intermittent porphyria [AIP] and variegate porphyria [VP] in Finland was studied. The diagnosis of hereditary hepatic porphyria was made in 152 cases, 107 of AIP (diagnostic criterion-elevated urinary porphobilinogen), and 45 of VP (diagnostic criterion: elevated fecal porphyrins). The prevalence of hereditary hepatic porphyrias in Finland was calculated to be 3.4/100,000 inhabitants (2.4/100,000 of AIP and 1.0/100,000 of VP). The AIP patients belonged to 35 families and the VP patients to 7 families. Porphyria was diagnosed in two or more successive generations in 20 families with AIP and in 6 families with VP. Eighty-nine patients had acute attacks and 63 patients were symptomless latent cases. Barbiturates (48 patients), infection (9 patients), sulphonamides (4 patients), and alcohol (3 patients) were the most usual precipitating factors in attacks. Fern extract (antihelminthic drug) was reported to be associated with porphyria. About 75% of patients were women. A slight fragilit of the skin on the back of the hands was reported in 50% of VP patients. In acute porphyria the serum protein-bound iodine (above 0.6 μM in 15/22 patients) and serum cholesterol (above 7.5 μM in 21/31 patients) were elevated. Disturbances in serum electrolytes were reported in 61% of the cases studied. The mortality in an acute porphyria attack was 30%. Fourteen percent of patients who survived an attack had later porphyria symptoms requiring hospitalization. The prognosis is better if porphyria is diagnosed in the latent stage.

5822 THE OPHTHALMOLOGIC MANIFESTATIONS OF WILSON'S DISEASE.

(Eng.) Wiebers, D. O.; Hollenhorst, R. W.; Goldstein, N. P. (Mayo Graduate Sch. Medicine, Univ. Minnesota, Rochester, MN). *Mayo Clin. Proc.* 52(7):409-416; 1977.

Ophthalmologic abnormalities were studied in 53 patients with Wilson's disease. Of the 35 symptomatic patients initially seen and treated, 34 had Kayser-Fleischer rings, and 6 had sunflower cataracts at the time of diagnosis. In patients followed for 1 yr or more, penicillamine therapy resulted in improvement of the Kayser-Fleischer rings in 18 of 20 patients and total clearing of the sunflower cataracts in 4 of 5 patients. The specific pattern of copper deposition in Kayser-Fleischer rings and the improvement with treatment occurred along four reproducible stages. None of five asymptomatic siblings of patients with known Wilson's disease had Kayser-Fleischer rings at the time of initial study. In one (untreated) of the five, Kayser-Fleischer ring developed 20 months after the initial normal slit-lamp examination. The presence of Kayser-Fleische rings, and the absence of other ophthalmologic sig (such as nystagmus, cranial nerve palsies, and other movement disorders), can be of great assistance in the diagnosis of Wilson's disease. Once the condition has been diagnosed, specific therapy with penicillamine and low-copper diet can dramati cally improve what would otherwise be a fatal cour

5823 FIXED DRUG ERUPTION INDUCED BY SULPHOBRO PHTHALEIN.

(Eng.) Smith, E. L. (Government Hosp., Abu Dhabi, Oman). *Br. J. Dermatol.* 97(1):106-107; 1977.

The case of a 50-yr-old woman who developed erythematous skin lesions 8 hr after undergoing an i.v. BSP liver function test is presented. The lesions were discrete, round, raised, and measured 1.5-2.5 cm in diameter. After 48 hr, they showed central

hyperpigmentation. The lesions subsided over the
next 2 weeks. The patient had developed similar
lesions 2 yr previously following the ingestion of
a laxative. This is the first reported case of fixed
drug eruption from BSP. The patient was sensitive to
phenolphthalein and appeared to be cross-sensitive to
3SP.

5824 THE CLINICAL PHARMACOLOGY OF A HEPATOMA-
SPECIFIC ALKYLATING AGENT. (Eng.) Curt,
G. A.; Connors, T. A.; Murray-Lyon, I. M.; Tattersall,
I. H. N. (Charing Cross Hosp., London W6 8RF, England).
Biochem. Pharmacol. 26(18):1715-1718; 1977.

he clinical and biochemical pharmacology of CB10-
52, a latent enzyme-activated alkylating agent, was
tudied in hepatoma patients. Following p.o. admin-
stration (30 mg), the drug was absorbed rapidly, and
eak levels of unmetabolized drug were seen at 1
r. The parent drug is cleaved by azoreductase to
ield an alkylating agent with a very short half-
ife and stable metabolites. Peak plasma levels
f these metabolites were seen at 2 hr, with per-
istence of the compounds for 12 hr. Eight hours
fter drug administration, 80% of the dose had
een eliminated in the urine, the majority in the
orm of metabolites with only 2% being recovered as
nmetabolized drug. Azoreductase activity was
emonstrated in normal human liver and in human
one marrow and lymphoid cells. This latter find-
ng may explain the occurrence of myelosuppression
bserved in several patients. These data indicate
hat CB10-252 is not a hepatoma-selective alkylating
gent, but that the drug is well absorbed following
.o. administration.

825 BILIARY DISPOSITION OF ADRIAMYCIN. (Eng.)
Riggs, C. E., Jr.; Benjamin, R. S.; Ser-
ick, A. A.; Bachur, N. R. (Baltimore Cancer Res.
enter, 3100 Wyman Park Dr., Baltimore, MD 21211).
lin. Pharmacol. Ther. 22(2):234-241; 1977.

ne biliary disposition of adriamycin was studied in
patient with a choledochal T tube and normal liver
unction who was receiving adriamycin as therapy
or abdominal histiocytic lymphoma. Plasma, urine,
nd bile samples were collected after drug admin-
stration (195 μM). Adriamycin and its metabolites
ere extracted from the samples and separated by
hin-layer chromatography. The pharmacokinetics
f adriamycin and its metabolites in plasma and
rine resembled those of previous patients, with
plasma elimination half-life for adriamycin of
.2 hr. Bile contained adriamycin and 11 metab-
lites, 4 of which were not present in plasma or
rine. Forty-one percent of the administered dose
adriamycin appeared in the bile in 7 days; of
is amount, 42% was adriamycin, 22% was adria-
cinol, the major metabolite, and 36% was other
etabolites. Hepatic clearances of adriamycin
d adriamycinol showed early, rapid removal of
ug by the liver, with subsequent slowing of re-
val rate as plasma drug concentration declined.
riamycin was more efficiently cleared than
riamycinol by both liver and kidney. Disease
states that impair the capacity of the liver to excrete adriamycin may result in prolonged, high drug levels and increased toxicity.

5826 ON THE MECHANISM OF LANTHANIDE-INDUCED LIVER TOXICITY. (Eng.) Sarkander, H. I.; Brade, W. P. (Pharmakologisches Institut der Freien Universitat Berlin, Thielallee 69-73, D-1000 Berlin 33, W. Germany). *Arch. Toxicol.* 36(1):1-17; 1976.

The effect of various rare earths on *in vitro* nuclear RNA synthesis in rat liver was examined to elucidate whether the primary cause for the massive liver damage after i.v. injection of rare earths in rats was localized at the subcellular level on the nucleic acid metabolic system and/or its nuclear regulative mechanisms. The i.v. injection (in doses of 3.5 μmol/100 g body weight) of the lighter lanthanide ions (praseodymium [Pr], neodymium, and samarium) inhibited and the heavier lanthanide ions (gadolinium, dysprosium, and erbium) stimulated rat liver nuclear RNA synthesis catalyzed by RNA polymerase B as measured 24 hr after the *in vitro* application of the ions. However, nuclear RNA synthesis catalyzed by RNA polymerase A was inhibited by iso-osmolar doses of lighter lanthanides and not influenced by the heavier lanthanides. The effect of Pr applied *in vivo* on rat liver *in vitro* nuclear RNA synthesis showed a time- and dose-dependent pattern. Twenty-four hr after i.v. Pr administration (150 μmol/kg body weight), RNA polymerases A and B were inhibited to 39.1 ± 2.9% and 19.4 ± 3.7%, resp., of control values (0.8 ± 0.08 and 2.6 ± 0.1 pmoles uridine monophosphate [UMP] incorporated/μg DNA, resp.). This decreased RNA synthesis was accompanied by a decreased nuclear *in vitro* ^{3}H-acetate uptake by the chromatin-bound histone fractions. The capacity of and number of initiation sites of the rat liver nuclear template for nuclear RNA polymerases, measured in the presence of the actinomycin D-insensitive synthetic template poly (dA-dT), was lower (26.7 ± 2.9 disintegrations per min [dpm]/μg DNA, of ^{3}H-UMP incorporation) in nuclei isolated from rats treated 24 hr previously with Pr than in control nuclei (50.8 ± 4.7 dpm/μg DNA of ^{3}H-UMP incorporation). It is concluded that the number of initiation sites of the nuclear template is diminished by the Pr treatment. A primary ionic size-correlated interference of lanthanides with the nuclear control mechanisms of RNA synthesis is suggested.

5827 THOROTRAST INJURY IN JAPAN. STATISTICAL STUDY ON AUTOPSY CASES AND FOLLOW-UP STUDY ON 147 CASES. (Jpn.) Mori, T.; Maruyama, T.; Hatakeyama, S.; Miyaji, T.; Tsuya, A.; Takahashi, S. (Dept. Pathology, Kanagawa Prefectural Junior Coll. Nursing and Technology, Japan). *Nippon Acta Radiol.* 35(6):439-452; 1975.

The incidence of Thorotrast liver injury was studied in Japan. Since 1945, 94 autopsy cases of patients exposed to Thorotrast were accumulated; among these, there were 60 cases of malignant liver tumors and

9 cases of blood diseases. Since approximately half of these patients were ex-servicemen, 147 ex-servicemen who received Thorotrast 31-36 yr previously were followed up. Among these, there were six with liver malignancies, one with leukemia, one with thrombocytopenic purpura, and five with liver cirrhosis. The incidences of these diseases were significantly higher than in a control group.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

5842 NEONATAL HYPERBILIRUBINEMIA: A COMPARISON BETWEEN PROSTAGLANDIN E_2 AND OXYTOCIN INDUCTIONS. (Eng.) Chew, W. C. (Queen Elizabeth Hosp., Kota Kinabulu, Sabah, Malaysia). *Br. Med. J.* 2(6088):679-680; 1977.

The incidence of neonatal hyperbilirubinemia was compared in infants of mothers in whom labor had been induced with oxytocin with that in those induced with prostaglandin E_2 (PGE_2). Forty-five mothers received PGE_2 p.o. (0.5-1 mg/hr) following amniotomy, and 45 received simultaneous low otomy and an i.v. oxytocin infusion. Controls isted of 45 women whose labor was spontaneous. mean serum bilirubin concentrations of infants vered after induction with oxytocin were sig- cantly higher ($p<0.01$) on the first, third, and n days postpartum (45.3 ± 10.2, 145.6 ± 47.0, 129.7 ± 48.5 μM, resp.) than the concentrations he infants delivered after spontaneous labor 0 ± 9.5, 94.0 ± 32.6, and 81.2 ± 32.6 μM, resp.). e was no significant difference ($p>0.05$) be- n the mean bilirubin levels in the infants of ers treated with PGE_2 and those in the infants others in whom labor was spontaneous. Using a n bilirubin level of less than 205 μM as within al limits in the neonatal period, elevated rubin levels occurred in 4%, 13%, and 2% of the nts of PGE_2-treated mothers, oxytocin-treated ers, and spontaneous mothers, resp. Induction abor with PGE_2 does not seem to carry the risk eonatal jaundice that oxytocin does.

BILIRUBINEMIC "REBOUND" AFTER PHOTOTHERAPY: IS IT A PROBLEM? (Ita.) Romagnoli, Pesaresi, M. A.; Polidori, G.; De Turris, P.; ldi, L. (Universita Cattolica del Sacro Cuore, Istituto di Clinica Pediatrica, Rome, Italy). *rva Pediatr.* 29(6):353-356; 1977.

A study was made of 73 low-birth-weight neonates being treated with phototherapy for bilirubinemia. Treatment was started within 12 hr of birth and continued for 4-6 days. Fifty-one percent of the infants treated for 4 days and 21% of those treated for 5 days had a rebound of bilirubinemia when treatment was stopped. Only 31% of those treated for 6 days had such a rebound. Rebound was directly related to gestational age as well as to length of treatment. It is suggested that treatment be continued for at least 6 days and perhaps longer in infants of very young gestational age. Caution is recommended in all cases, and bilirubinemia should be monitored for several days after the suspension of treatment.

5844 WHY HYPERBILIRUBINEMIA AND HYPOALBUMINEMIA PREDISPOSE TO STEROID SIDE EFFECTS DURING TREATMENT OF CHRONIC ACTIVE LIVER DISEASE (CALD) [Abstract]. (Eng.) Uribe, M.; Summerskill, W. H. J.; Go, V. L. W. (Mayo Clinic, Rochester, MN). *Gastroenterology* 72(5):1143; 1977.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

LIVER TOXICITY AFTER ACETAMINOPHEN INGESTION: INADEQUACY OF THE DOSE ESTIMATE INDEX OF RISK. (Eng.) Ambre, J.; Alexander, niv. Iowa Hosp., Iowa City, IA 52242). *JAMA*):500-501; 1977.

isk of hepatic necrosis was assessed in five nts who had taken an overdose of acetaminophen; ase reports are presented. The patients re- d that they had taken 10-50 g of acetaminophen. er, the plasma levels at the time of admission, the induction of emesis, or after the admin- tion of activated charcoal, were less than 5 to 20 μg/ml in three patients. In one of emaining patients, the level after charcoal istration was 150 μg/ml, and the acetaminophen life was estimated to be 1.75 hr. The level 3 μg/ml in the fifth patient, the half-life 2 hr. Antidotal therapy was instituted with lcysteine (7.5 g) in only one patient, because the plasma acetaminophen level had been miscalculated to be 200 μg/ml. Hepatotoxicity did not occur in any patient. It appears that estimating the dose of acetaminophen ingested is inadequate as an index of the risk of hepatotoxicity and that the measurement of plasma acetaminophen levels is a much more reliable index of the amount actually absorbed.

5847 HEPATOTOXICITY OF DEXTROPROPOXYPHENE. (Eng.) Lee, T. H.; Rees, P. J. (Guy's Hosp., London SE1, England). *Br. Med. J.* 2(6082):296-297; 1977.

The cases of two patients with dextropropoxyphene-induced liver damage are presented. The first patient, a 56-yr-old man, experienced recurrent episodes of jaundice for 5 yr, during which time his usual analgesic was codeine. Ten days after first taking Distalgesic (dextropropoxyphene, 32.5 mg + paracetamol, 325 mg), he developed jaundice, dark urine, pale stools, and abdominal pain. This occurred after two further exposures to the analgesic, and there was a decrease in the time between exposure and the appearance of symptoms. When he was challenged with 130 mg of dextropropoxyphene, he developed the same symptoms within 24 hr, with associated abnormal liver function tests. Subsequent exposure to paracetamol alone was uneventful. The second patient, a 66-yr-old woman who was receiving thyroxine, cyclopenthiazide, and potassium chloride in addition to Distalgesic, reported feeling tired 1 month after the institution of therapy; the liver function tests were abnormal. The symptoms resolved 5 days after discontinuing the analgesic. When challenged with 130 mg dextropropoxyphene, she developed the same symptoms within 24 hr. The decrease in time between exposure to Distalgesic and abnormal liver function with repeated exposures and the relatively small dose of dextropropoxyphene required to reproduce the changes suggest a sensitivity reaction. The episodes of jaundice occurring during 5 yr in the first patient may have been due to cross-sensitivity to codeine.

5848 DISULFIRAM HEPATOTOXICITY. (Eng.) Ranek, L.; Andreasen, P. B. (Righospitalet, DK-2100 Copenhagen, Denmark). *Br. Med. J.* 2(6079):94-96; 1977.

The cases of six alcoholic patients who developed liver damage after the institution of aversion therapy with disulfiram are presented. The patients had been treated with disulfiram (200 mg/day) for 2 weeks to 6 months before the onset of symptoms. Only one patient had liver disease when disulfiram treatment was started. All but one patient died in hepatic coma; in the remaining patient, hepatitis due to disulfiram was confirmed by a challenge test. A liver biopsy 5 days later showed portal enlargement with infiltration of inflammatory cells and eosinophil leukocytes and focal necrosis in the parenchyma. The symptoms of anorexia, vomiting, abdominal pain, and fever lasted for 6 days. Liver biopsies 5 and 11 yr later were normal. In the other five patients, necropsy revealed a small liver with liver cell necrosis and fibrosis. These findings indicate that long-term toxicity studies in animals should be carried out to detect possible liver damage after prolonged administration of disulfiram.

5849 DRUG-INDUCED LIVER CELL GRANULOSIS (BASED ON TWO CASES). (Heb.) Litvin, I.; Brotver, N. (Hadassah Hosp., Jerusalem, Israel). *Harefuah* 89(10):474-475; 1975.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

5851 THE EFFECT OF 1-β-D-RIBOFURANOSYL-1,2,4-TRIAZOLE-3-CARBOXAMIDE ON ACUTE VIRAL HEPATITIS. (Eng.) Ayrosa-Galvao, P. A.; Castro, I. O. (ICN Pharmaceutical, Inc., Irvine, CA 92715). *Ann. N.Y. Acad. Sci.* 284:278-283; 1977.

A double blind study was conducted to verify the therapeutic action of 1-β-D-ribofuranosyl-1,2,4-triazole-3-carboxamide (ribavirin) during the first 10 days of treatment of acute viral hepatitis. Among 66 patients studied, 33 were randomized to receive one capsule of ribavirin (0.100 g) every 6 hr for 10 consecutive days, while another 33 patients received capsules of placebo on the same schedule. On the day before capsule administration, the total (STB) and direct (SDB) bilirubin, SGOT, and SGPT values were 12.40 mg/100 ml, 8.42 mg/100 ml, 1,286.00 IU/ml, and 1,184.12 IU/ml, resp., for patients randomized to receive ribavirin; the values for patients randomized to receive the placebo were 9.86 mg/100 ml, 6.28 mg/100 ml, 1,111.35 IU/ml, and 1,056.70 IU/ml, resp. The STB values i the ribavirin group declined a total of 36% ($p<0.0$ by day 5 of treatment as compared with 25.4% ($p<0.$ for the placebo group; by day 10, the ribavirin group showed a 58.5% decline ($p<0.01$), as compared with 39.6% ($p>0.05$) for the placebo group. Simila ly, SDB values were reduced by 37.0% ($p<0.01$) and 19.0% ($p>0.05$) by day 5 and by 60.0% ($p<0.01$) and 36.0% ($p>0.05$) by day 10 in the ribavirin and placebo groups, resp. SGOT was reduced by 60.0% ($p<0.01$) and 50.0% ($p<0.01$) by day 5 and 78.0% ($p<0.01$) and 55.0% ($p>0.05$) by day 10 in the ribavirin- and placebo-treated patients, resp. SGPT

els were reduced 54% ($p < 0.01$) and 42.0% ($p < 0.05$)
day 5 and 77.0% ($p < 0.01$) and 55.0% ($p > 0.05$) by
10 in the ribavirin and placebo groups, resp.
se data indicate that the rate of recuperation
significantly increased in patients treated with
avirin, especially after the 5th day of treatment.
effects of ribavirin on human viral hepatitis
presumed to be due to a direct antiviral action,
ce this drug has significant effects on viral
ections both *in vitro* and in laboratory animals.

2 COENZYME-B_{12} THERAPY IN ACUTE VIRAL HEPATITIS.

(Eng.) Iwarson, S.; Lind-
g, J. (Ostra Sjukhuset, S-41685 Goteborg, Sweden).
nd. J. Infect. Dis. 9(2):157-158; 1977.

therapeutic effect of coenzyme-B_{12} in hepatitis
as compared with that of hydroxycobalamin in two
ups of patients from the same epidemic of short
ubation hepatitis A. Twenty patients received
roxycobalamin (1 mg/day, i.v., 12 days followed
mg/day, p.o., until a total period of 35 days).
nty patients received the same dose levels of
nzyme-B_{12} for the same periods. At the second,
rd, fourth, and fifth weeks after the onset of
ndice, the serum SGPT levels were abnormal (>25
in 90%, 70%, 30%, and 15% of the coenzyme-
ted patients, resp., while the same values in
cyanocobalamin-treated group were 100%, 80%,
and 35%. The SGOT levels in the coenzyme-
ted group were 80%, 30%, 20%, and 10%, resp., and
50%, 40%, and 30% in the cyanocobalamin-treated
p. The results show that aminotransferase lev-
of the patients treated with coenzyme-B_{12} tended
ormalize more rapidly than those of the patients
ted with cyanocobalamin. A statistically sig-
cant difference in the SGOT level appeared in
fourth week ($p < 0.05$) between the two groups.
zyme-B_{12} may have clinical value in the treat-
of viral hepatitis.

THERAPY OF VIRAL HEPATITIS B. PRACTICAL CONSEQUENCES.

(Ger.) Kuhn, H. A. (Med-
sche Universitatsklinik, D-8700 Wurzburg, W.
ny). *Schweiz. Med. Wochenschr.* 107(15):514-
1977.

onspecific general therapy, drug treatment and
otherapy of viral hepatitis is discussed.
ally, in uncomplicated courses of hepatitis A
bed rest and isolation are recommended.
ment with prednisone and corticoids has resul-
n a rapid drop in serum bilirubin concentra-
and a decrease in transaminase values. How-
the rate of B hepatitis carriers has been
ted possibly to be greater after corticoid
py. The effectiveness of glucocorticoids in
nant hepatitis is still controversial and may
d on early drug administration. Of 58
nts that were treated with hepatitis B
ce antigen (HBsAg)-rich human serum for
nant hepatitis B, 24 survived. On the other
the administration of azathioprine with glu-
ticoids is highly effective in chronic active
tis regardless of the presence of HBsAg in

the plasma. The best results have been noted in patients with lupoid hepatitis. The use of transfer factor, levamisole, or thymosine to suppress T-cell action on antibody production of the B cells has not been fully evaluated in treating chronic active hepatitis. Overall, prophylaxis is important in hepatitis B infections. Recent studies with active immunization with vaccines from HBsAg-rich sera or of purified formalin-inactivated HBsAg preparations suggest the possibility of successful prophylaxis against hepatitis B. However, suitable culture media for the virus must be found so that a sufficient quantity of vaccine can be produced.

5854 POSSIBILITIES FOR THE EVALUATION OF THE INFECTIVITY OF HBsAG-POSITIVE PERSONS.

(Ger.) Stalder, G. A. (Medizinische Universitats-Poliklinik, Hebelstrasse 1, CH-4056 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 107(18):614-617; 1977.

The possibility of deducing the risk of infection of contacts by subjects with hepatitis B surface antigen (HBsAg)-positive blood is discussed. Only blood containing the virion formed from HB core antigen (HBcAg) and HBsAg (DANE particles) is infective. DANE particles have been found in patients with chronic aggressive and other forms of hepatitis all belonging to the HBc+s-type. The blood of HBsAg-positive patients receiving immunosuppressive therapy contains DANE particles and is considered highly infectious. However, since a patient can be clinically asymptomatic, a light-microscopic evaluation of the liver is recommended in an HBsAg carrier. In chronic aggressive or acute hepatitis, treatment with prednisone or with Imuran results in clinical and histological improvement of the liver, although it may increase the production of DANE particles. Few or no DANE particles are found in patients with spontaneous acute hepatitis B. The relation of the HBs- and HBc-antigen-antibody system has also been studied, and the role of DNA polymerase, HBc-antigen, or e-antigen in providing data on the infectivity of HBsAg blood has yet to be elucidated.

5855 PASSIVE IMMUNIZATION AGAINST EXPOSURE TO HEPATITIS B VIRUS IN THE MILITARY: POTENTIAL AND POSSIBILITIES.

(Eng.) Irwin, G. R. (Walter Reed Army Medical Center, Washington, DC 20012). *Yale J. Biol. Med.* 49(3):251-257; 1976.

The value of standard γ-globulin with a low titer of antibody to hepatitis B surface antigen (anti-HBs) versus hepatitis B immune globulin (HBIG) in prevention of icteric hepatitis B in the military is reviewed. Although recent studies have shown a decrease in icteric hepatitis after administration of both types of γ-globulin in populations where acquisition of hepatitis B virus (HBV) is most likely the result of nonparenteral transmission, the data pertaining to parenteral exposure suggest that HBIG delays the incubation period of HBV and decreases the the incubation period of HBV and decreases the development of passive-active immunity. Since no studies have demonstrated the efficacy of standard γ-globulin or HBIG in a drug-using population where multiple HBV exposures are likely, the results observed in most trials are not comparable to hepatitis B associated with drug abuse in the military. The attack rate of HBV in U.S. Army Divisions in Germany was reported to be 12-15/1,000 in 1975. Illicit drug use is reported as the major reason for increasing hepatitis rates in the U.S. Army. Therefore, it is suggested that, before a recommendation for use of routine γ-globulin or HBIG can be made for drug-related hepatitis in the military, the efficacy of standard γ-globulin and/or HBIG should be demonstrated in this population.

5856 DISPARATE RESPONSE OF MONOZYGOTIC TWINS TO HEPATITIS B VIRUS INFECTION. (Eng.)

Peters, C. J.; Reeves, W. C.; Purcell, R. H. (Sch. Public Health and Community Medicine, SC-36, Univ. Washington, Seattle, WA 98195). *J. Pediatr.* 91(2): 265-266; 1977.

The cases of monozygotic twins who were discordant for hepatitis B antigenemia are presented. One twin developed hepatitis at the age of 10 yr. Two weeks after the onset of symptoms, his serum did not contain hepatitis B surface antigen (HBsAg) when tested by gel diffusion, counterelectrophoresis, complement fixation, or radioimmunoassay. However, antibody to HBsAg (anti-HBs) was detected by radioimmunoprecipitation. His serum IgM concentration was 437 IU/ml in the initial sample and had decreased to 135 IU/ml 4 weeks later. Subsequent tests for HBsAg and anti-HBs performed 1 month and 2 yr later gave identical results. The patient's identical twin had serum HBsAg detectable by complement fixation, counterelectrophoresis, and gel diffusion. His HBsAg persisted through 2 yr at a complement fixation titer of 1:512. The propositus probably suffered from hepatitis A, as anti-HBs is not usually detectable by radioimmunoassay 2 weeks after the onset of hepatitis B; in addition, the high IgM level suggests hepatitis A infection. The data support the contention that two genetically identical human beings have encountered HBsAg with chronic antigenemia resulting in one and an antibody response in the other. This observation supports open population studies that indicated that the interactions between host genome and a variety of epidemiologic factors ultimately determine the chronic carrier state.

5857 NEONATAL HEPATITIS IN FIVE CHILDREN OF A HEPATITIS B SURFACE ANTIGEN CARRIER WOMAN.

(Eng.) Mollica, F.; Musumeci, S.; Fischer, A. (Clinica Pediatrica Universita, Viale A. Doria, 95125 Catania, Italy). *J. Pediatr.* 90(6):949-950; 1976.

The transmission of hepatitis from an asymptomatic hepatitis B surface antigen (HBsAg)-positive mother to her six children during a 22-yr period is reported. Four infants developed symptoms of hepatitis at the age of 1-2 months and died at the ages of 38-75 days. One child had an uneventful neonatal period and is in good health at 22 yr of age; he was found to have persistent HBsAg antigenemia. Th sixth-born child developed hepatitis at 2.5 months. After receiving a total of 520 ml of ABO compatible fresh plasma from three donors who had recently had hepatitis B, and that contained high titers of antibodies to HBsAg, clinical improvement and a decrease in serum bilirubin values to normal ensued The child is clinically well at age 3.5 yr, and no jaundice or antigenemia is present. This case study shows that an asymptomatic HBsAg carrier mother may transmit the antigen, and consequently the disease, to successive children for as long as 22 yr. The authors believe that infusions of hepatitis B immune plasma might have contributed to the favorable evolution of the disease in the sixth child.

5858 HEPATITIS B SURFACE ANTIGEN AND CHRONIC HEPATITIS IN INFANTS BORN TO ASYMPTOMATIC CARRIER MOTHERS.

(Eng.) Shiraki, K.; Yoshihara, N.; Kawana, T.; Yasui, H.; Sakurai, M. (Dept. Pediatrics, Univ. Tokyo, 7-3-1 Hongo, Bunkyo-ku, Toky 113, Japan). *Am. J. Dis. Child.* 131(6):644-647; 1977.

Twenty-three infants born to asymptomatic hepatiti B surface antigen (HBsAg) carrier mothers were followed up to determine whether hepatitis B virus is transmitted vertically from these mothers. Four infants became positive for HBsAg within 4 months after birth. Three showed hepatic dysfunction; liver biopsy specimens demonstrated mild chronic hepatitis in one and persistent hepatitis in another. In six infants followed up for more than 6 months after birth, antibody to HBsAg (anti-HBs) without antigenemia was detected. Antigenemia of cord blood strongly suggested that hepatitis B viral infection of the infant would occur. HBsAg was also demonstrated in breast milk by radioimmun assay in three of nine cases. These findings indi cate that vertical transmission of hepatitis B virus occurs in many infants born to asymptomatic HBsAg carrier mothers, and that some of them becom persistent carriers or develop chronic hepatitis without showing any signs suggesting hepatic involvement.

5859 ETIOLOGY OF SPORADIC HEPATITIS B SURFACE ANTIGEN-NEGATIVE HEPATITIS. (Eng.)

Dienstag, J. L.; Alaama, A.; Mosley, J. W.; Redeke A. G.; Purcell, R. H. (Massachusetts General Hosp. Boston, MA 02114). *Ann. Intern. Med.* 87(1):1-6; 1977.

The etiology of 45 cases of sporadic acute viral hepatitis B surface antigen (HBsAg)-negative hepa was investigated. Two cases were due to hepatiti virus, as demonstrated by the appearance of antib to hepatitis B core antigen. In three other pati the serologic pattern was inconclusive. Of 40 no cases, 20 were type A hepatitis and 20 were non-A non-B hepatitis. Clinically, type A and non-A, n hepatitis were indistinguishable; one case of ful nant disease occurred in each group. The type A cases were more frequent in young adults; non-A, disease predominated in women 35 yr or older. Ep

lemiologic backgrounds were similar, including illi-
:it self-injection; but four transfusion-associated
:ases were limited to the non-A, non-B group. It is
:oncluded that relatively few HBsAg-negative cases
ıre due to hepatitis B virus, and that hepatitis A
irus and non-A, non-B viruses are both important in
ıcute non-B disease.

860 MONONUCLEAR CELL MIGRATION TEST WITH
MITOCHONDRIAL ANTIGENS IN HBsAg ACUTE
EPATITIS. (Eng.) Bianchi, F. B.; Zauli, D.;
archesini, G.; Pisi, E. (Istituto di Patologia Spe-
iale Medica I, Policlinico S. Orsola, Via Massarenti,
, 40100 Bologna, Italy). *Rend. Gastroenterol.* 9
1):1-3; 1977.

he leukocyte migration inhibition (LMT) test was car-
ied out in the mononuclear cells and the polymorphs
f 10 patients who were positive for acute hepatitis
surface antigen (HBsAg). Migration of lympho-
ytes was inhibited by the presence of human fetal
iver mitochondria (57.5 or 115 µg/ml) in 7 of the
) patients. The total leukocytes were inhibited
ı 8% of the cases by 57.5 µg/ml of the antigen,
ıd in 19% of the cases by 115 µg/ml. The poly-
ırphs showed no response. This study suggests that
ıe mononuclear cells respond in LMT tests of HBsAg-
ısitive hepatitis.

61 LOCALIZATION OF HBc-Ag AND HBs-Ag IN THE
LIVER TISSUE. (Jpn.) Yoshizawa, H.;
ta, G.; Sugioka, G.; Sugimoto, T. (Sch. Medicine,
nazawa Univ., Japan). *Jpn. J. Gastroenterol.* 73
):22-30; 1976.

e localization of intrahepatic hepatitis B core
tigen (HBcAg) and hepatitis B surface antigen
BsAg) was examined by an immunofluorescent anti-
dy technique and by electron microscopy in tissue
om 29 patients with acute hepatitis, 49 with
ronic active hepatitis, 22 with chronic inactive
patitis, 22 with liver cirrhosis, 7 with hepatoma
d liver cirrhosis, 19 asymptomatic antigen car-
ers, and 7 with normal liver. HBcAg was detected
ly in the hepatocyte nuclei, but HBsAg was found
the cytoplasm, using the immunofluorescent anti-
dy technique. In all of nine livers with intra-
clear fluorescence specific for HBcAg, core-like
rticles were detected in the hepatocyte nuclei
ing electron microscopy. Aggregates of core-like
rticles were isolated from tissue in which many
cAg-positive nuclei were detected by immunofluo-
scent microscopy. The intranuclear core-like
rticles may represent HBcAg.

52 THE PROTEINS OF HEPATITIS B DANE PARTICLE
CORES. (Eng.) Hruska, J. F.; Robinson,
S. (Stanford Univ. Sch. Medicine, Stanford, CA
05). *J. Med. Virol.* 1(2):119-131; 1977.

peptides of the hepatitis B Dane particle cores
e studied. Dane particles and Dane particle
es (produced by NP-40 treatment of Dane particles)
e purified by equilibrium centrifugation in CsCl density gradients. Two populations of Dane particles were observed at densities 1.27 and 1.24 g/ml, resp. The higher buoyant density Dane particles yielded exclusively cores of buoyant density of 1.38 g/ml in CsCl, and the lower buoyant density Dane particles yielded two kinds of cores with buoyant densities of 1.38 and 1.325 g/ml, resp. Only the higher density Dane particles and cores manifested endogenously primed DNA polymerase activity. The peptides of density 1.38 g/ml Dane particle cores purified by equilibrium CsCl density gradient centrifugation and hepatitis B core antigen (HBcAg) particles from hepatitis B virus (HBV)-infected chimpanzee liver purified in the same way were analyzed by sodium dodecyl sulfate polyacrylamide gel electrophoresis. Both kinds of particles were found to consistently contain 3 Coomassie blue staining peptides, with approximate molecular weights of 19,000, 70,000, and 80,000 daltons (designated P-19, P-70, and P-80, resp.). In addition, the HBcAg particles from infected liver regularly yielded a protein component with molecular weight greater than 200,000 daltons. This component was occasionally present in electrophoresis runs of core peptides from only one of two patients. Its irregular appearance after gel electrophoresis suggests that it may have been an aggregate not completely dissociated under the conditions used. The lower density core component consistently contained P-19, P-70, and P-80, and infrequently, additional minor peptides of uncertain origin. The irregular occurrence of the minor peptides in varying amounts suggests they were not intrinsic core proteins.

5863 ASSOCIATION OF e ANTIGEN WITH DANE PARTICLE DNA IN SERA FROM ASYMPTOMATIC CARRIERS OF HEPATITIS B SURFACE ANTIGEN. (Eng.) Werner, B. G.; O'Connell, A. P.; Summers, J. (Fox Chase Cancer Center, Philadelphia, PA 19111). *Proc. Natl. Acad. Sci. U.S.A.* 74(5):2149-2151; 1977.

The prevalence of the e antigen (HBeAg) was determined in 30 asymptomatic hepatitis B surface antigen (HBsAg) carriers, and the hypothesis that HBeAg is a marker of potential hepatitis B virus infectivity was tested. Fourteen samples (47%) had HBeAg detectable by rheophoresis, 10 (33%) had antibody to HBeAg (anti-HBe), and 6 (20%) had neither. DNA was extracted from 26 of these sera and assayed for its ability to anneal to a [^{32}P]-DNA probe that is a copy of Dane particle DNA. All 10 HBeAg-positive samples tested contained DNA that formed specific hybrids with the DNA probe, as did 1 of 10 anti-HBe-positive samples. Hybridization was not detected in nine sera containing anti-HBe and six sera without HBeAg or anti-HBe. Because the Dane particle is thought to be the hepatitis B virus, this association between HBeAg positivity and Dane particle DNA supports the hypothesis that e antigen is a marker of the presence of the virus and, consequently, potential infectivity.

5864 CORRELATION OF e ANTIGEN, DNA POLYMERASE ACTIVITY, AND DANE PARTICLES IN CHRONIC

BENIGN AND CHRONIC ACTIVE TYPE B HEPATITIS INFECTIONS.
(Eng.) Tong, M. J.; Stevenson, D.; Gordon, I. (Rancho Los Amigos Hosp., 12733 Erickson Ave., Downey, CA 90242). *J. Infect. Dis.* 135(6):980-984; 1977.

The relationship between the e antigen, DNA polymerase activity, and Dane particles was investigated in 42 hepatitis B surface antigen (HBsAg) carriers with persistent viral hepatitis or chronic active type B hepatitis. The e antigen occurred in 23 of the 42 subjects. The presence of e antigen was associated with increases in DNA polymerase activity and in the number of circulating Dane particles. In the group with detectable e antigen, the average DNA polymerase activity was 367 ± 78 counts/min (cpm), and the average number of Dane particles counted in electron micrographs was 4.4% of the total HBsAg. In contrast, e antigen-negative patients had an average DNA polymerase activity of 40 ± 6.9 cpm ($p<0.1$) and an average Dane particle count equal to 0.6% of the HBsAg carriers or had persistent viral hepatitis and 40% of those with chronic active type B hepatitis. Thus, the presence of e antigen correlated with both the chronicity and presence of infectious HBV. However, it did not correlate with the type or severity of liver disease after HBV infection, since e antigen was present in both chronic benign and chronic aggressive hepatitis B infections.

5865 ANTIBODIES TO HEPATITIS B CORE ANTIGEN IN HEPATITIS B SURFACE ANTIGEN-POSITIVE AND -NEGATIVE CHRONIC HEPATITIS.
(Eng.) Gerber, M. A.; Zappi, T.; Vernace, S. J.; Paronetto, F. (Mount Sinai Sch. Medicine, Fifth Ave. and 100th St., New York, NY 10029). *J. Infect. Dis.* 135(6):1006-1009; 1977.

The possibility that antibody to hepatitis B core antigen (anti-HBc) is a marker of hepatitis B virus (HBV) infection in patients with chronic hepatitis was studied. One hundred twenty-four sera from 67 patients with histologically proven chronic hepatitis were tested by the indirect fluorescent antibody technique. All patients, except for one with chronic hepatitis who was seropositive for hepatitis B surface antigen (HBsAg), had anti-HBc that persisted throughout the follow-up period (3 months-3 yr). Of 33 HBsAg-seronegative patients, anti-HBc was detected in 7 and persisted for 6 months to 2 yr. These findings suggest that 21% of patients with chronic hepatitis with undetectable amounts of HBsAg in the serum had evidence of recent or continued HBV replication.

5866 HEPATITIS B CIRCULATING IMMUNE COMPLEXES. CHARACTERIZATION BY RADIOIMMUNOPRECIPITATION-PEG ASSAY (RIPEGA).
(Eng.) Santoro, F.; Wattre, P.; Dessaint, J. P.; Capron, A. (Service d'Immunologie et de Biologie Parasitaire, Faculte de Medecine, Place de Verdun and Institut Pasteur de Lille, 20, boulevard Louis XIV, 59012 Lille cedex, France). *J. Immunol. Methods* 15(3):201-209; 1977.

The incidence of circulating immune complexes (IC) in carriers of hepatitis B antigen (HBAg) and/or anti-HB antibodies (anti-HBAb) was investigated using the three methods: a radioiodinated C1q binding test (C1q-BT), a complement fixation test, and optical density measurement after dissolution of a 3% polyethylene glycol (PEG) precipitate of the test serum. A highly significant correlation ($p<0.001$) was found between the three techniques. The level of circulating IC was significantly higher in carriers of HBAg and/or anti-HBAb than in normal control subjects, with more than 70% of the carriers having circulating IC levels higher than controls. Carriers of HBAg without detectable anti-HBAb had IC levels higher than those of patients with detectable anti-HBAb ($p<0.001$). The characterization of HBAg and anti-HBAb in IC was performed using a radioimmunoprecipitation-PEG assay (RIPEG). This sensitive and reproducible test was performed by incubation of ^{125}I-HBAg or ^{125}I-anti-HBAb with a 3% precipitate of the carrier's sera. Separation of free from complexed ^{125}I-HBAg or ^{125}I-anti-HBAb was achieved by PEG precipitation. A significant correlation was observed between the levels of HBAg or anti-HBAb in 3% PEG precipitates and the quantities of circulating IC ($p<0.001$) as determined by C1q-BT. When RIPEG was used to quantify HBAg and anti-HBAb in the sera of HBAg or anti-HBAb carriers and normal subjects, the mean values for the precipitation of ^{125}I-HBAg and ^{125}I-anti-HBAb for control subjects (5.1 ± 1.3 and 5.5 ± 1.1%, resp.) were lower than those for carriers of HBAg without anti-HBAb (6.8 ± 1.9 and 21.4 ± 11%, resp.) or carriers of anti-HBAb without HBAg (27.2 ± 17.6 and 7.7 ± 2.6%, resp.). RIPEG appeared to be more sensitive than classical radioimmunoassay for detecting serum HBAg and anti-HBAb.

5867 ACUTE HEPATITIS: SIGNIFICANCE OF CHANGES IN COMPLEMENT COMPONENTS.
(Eng.) Charle worth, J. A.; Lawrence, S.; Worsdall, P. A.; Roy, L. P.; Boughton, C. R. (Prince Henry Hosp., Little Bay, N.S.W. 2036, Australia). *Clin. Exp. Immunol.* 28(3):496-501; 1977.

Serial measurements of complement components were carried out in 59 patients with acute, uncomplicated hepatitis and 12 with alcoholic cirrhosis. Thirty-one hepatitis patients had detectable hepatitis B antigen. Abnormal complement profiles were observed in nine patients with hepatitis B and seven with antigen-negative hepatitis. Low levels of C4, C3, and factor B were common in the subjects with cirrhosis and confined to those cases with severe reduction in serum albumin and/or prothrombin index. The complement changes in the patients with hepatitis occurred without significant alteration in these parameters; certain subjects also had reduction in C1q and C5, and a significant number had C3d detectable in fresh plasma. The pattern of abnormality suggests predominant involvement of the classical pathway, and this may result, at least in part, from an immune process evident only in the early clinical phase of hepatitis. Such gross changes in complement are likely to reflect immune-complex activity, and these complexes may be im-

tant in the clearance of virus material. The
a support a previous suggestion that recovery
m acute hepatitis is primarily dependent on
t immune competence rather than viral cytotox-
ty or generation of immune complexes.

8 HLA-A1, B8-PHENOTYPE ASSOCIATION AND HBs
ANTIGENEMIA EVOLUTION IN 440 HEMODIALYZED
IENTS. (Eng.) Descamps, B.; Jungers, P.; Naret,
Degott, C.; Zingraff, J.; Bach, J. F. (Hopital
ker, Unite 25 Inserm, F-75730 Paris Cedex, France).
estion 15(4):271-277; 1977.

determine whether there is a greater immune
ponse in patients able to eliminate hepatitis B
face antigen (HBsAg) and to study the possible
ation between HBsAg antigenemia and the develop-
t of active chronic hepatitis, the sera of 440
odialyzed patients was tested by electroimmuno-
fusion and radioimmunoassay monthly for the pre-
ce of HBsAg. The sera were typed for 26 histo-
patibility antigen (HLA) alleles of the A and B
i. An abnormally high rate of the HLA-A1,B8
ociation (18.6%) was found in patients able to
inate HBsAg, when compared with the normal French
lation (5.05%, $p<10^{-4}$), and with patients unable
eliminate HBsAg (7.0%, $p<0.01$). Chronic aggres-
e hepatitis was only found in the latter. This
frequency of the HLA-A1,B8 association has also
found in patients with seronegative active
nic hepatitis and suggests that this phenotype
t be associated with high immune response against
g.

CONCENTRATIONS OF PLASMA GLYCOSPHINGOLIPIDS
IN ACUTE HEPATITIS. (Ger.) Atzpodien, W.;
ls, G.; Kremer, G. J.; Schnellbacher, E. (II.
Klinik und Poliklinik der Universitat, Langen-
strasse 1, D-6500 Mainz, W. Germany). *Klin.
enschr.* 55:457-459; 1977.

ma glycosphingolipid levels were determined in
atients with acute hepatitis in the acute and
acute phases of the disease and compared to
levels in 23 healthy controls. Blood samples
taken after 12 hr of fasting; monohexosyl,
xosyl, trihexosyl, and tetrahexosyl ceramide
determined by gas chromatography. In the acute
e of hepatitis, the glycosphingolipid fractions,
the exception of trihexosyl ceramide, showed
istically significant elevations in comparison
controls. Furthermore, cholesterin (acute:
± 96 mg/100 ml; postacute: 227 ± 43 mg/100 ml)
triglyceride (acute: 211 ± 65 mg/100 ml; post-
e: 129 ± 54 mg/100 ml) levels showed statis-
lly significant elevations ($p<0.01$) in compar-
with controls. The results suggest that the
eased plasma glycosphingolipid levels are a
bolic consequence of hyperlipoproteinemia and
they are in part synthesized *de novo* by the
r in a manner similar to very-low-density
proteins.

VASCULITIS IN HEPATITIS B INFECTION. (Ger.)
Muller-Schoop, J.; Gerber, N.; Knoblauch,
M. (Medizinische Klinik, Kantonspital, Ramistrasse 100, CH-8091 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 107(15):523-525; 1977.

The association of hepatitis B (HB) infection with various forms of vasculitis was investigated in 11 patients with polyarteritis nodosa and HB and 20 patients with recent giant cell arteritis (polymyalgia rheumatica and temporal arteritis). Hepatitis B surface antigen (HBsAg) and anti-HBsAg were measured by radioimmunoassay. Of the 11 patients with polyarteritis nodosa, 4 had a positive HBsAg test at every testing period, indicating a hepatitis B infection. Liver changes in these four patients did not correlate with the activity of periarteritis: one patient each had cirrhosis, chronic aggressive hepatitis, and chronic persistent hepatitis, whereas one patient who had no biopsy showed no biochemical liver changes. Anti-HBsAg was found in 7 of 20 patients with giant cell arteritis as compared with only 6% of the controls, but no concurrent liver disease was found in these patients. The results suggest that periarteritis in HBsAg-positive patients represents a rare but serious extrahepatic complication of hepatitis B infection. Evidently, circulating HBsAg/anti-HBsAg complexes play an important role in the development of HB-associated vasculitis.

5871 DETECTION OF HEPATITIS A ANTIBODIES AND ANTIGENS IN THE DIAGNOSIS OF HEPATITIS A INFECTION. (Ger.) Frosner, G. G. (Max-von-Pettenkofer-Institut fur Hygiene und Medizinische Mikrobiologie der Universitat, Pettenkoferstrasse 9 a, D-8000 Munchen 2, W. Germany). *Munch. Med. Wochenschr.* 119(24):825-828; 1977.

Hepatitis A antigen (HA-Ag) and antibodies were studied by radioimmunology and competitive solid phase radioimmunoassay for the diagnosis of HA infection. Centrifuged stool samples were incubated with ^{125}I-labeled HA-Ag for 16 hr for the determination of HA antigens; serum HA antibodies were measured by the extent of inhibition of the binding of ^{125}I-labeled HA-Ag. The fecal excretion of HA-Ag depended upon the severity of the disease. A patient with a slight subclinical infection excreted small amounts of HA-Ag for only 2 days, whereas HA-Ag excretion was already detected 11 days before the appearance of icterus in severe cases, reaching its maximum 6 or 7 days prior to the appearance of icterus; HA-Ag was detected in the stool of 50% of 101 patients with HA in the first week after the appearance of icterus, in 29% in the second week, and in only 4% in the third week. Low serum HA-Ag levels were demonstrated by radioimmunology with the appearance of icterus in 892 patients. The HA-Ag titer rose steeply in the first 2 weeks after the appearance of icterus attaining a maximum 3-5 months after start of the disease.

5872 HEPATITIS TYPE A AND HEMODIALYSIS: A SERO-EPIDEMIOLOGIC STUDY IN 15 U.S. CENTERS. (Eng.) Szmuness, W.; Dienstag, J. L.; Purcell, R. H.; Prince, A. M.; Stevens, C. E.; Levine, R. W.

(New York Blood Center, 310 E. 67 St., New York, NY 10021). *Ann. Intern. Med.* 87(1):8-12; 1977.

To assess the significance of dialysis in the spread of hepatitis A virus infections, 460 patients and staff from 15 U.S. dialysis centers were surveyed by the immune adherence hemagglutination technique for antibody to hepatitis A antigen (anti-HA). The age-standardized anti-HA prevalence was 42.9% in patients and 42.1% in staff. These rates are almost identical to those of socioeconomically comparable urban volunteer blood donors never exposed to dialysis settings. There was no correlation between anti-HA prevalences and duration of dialysis treatment or employment. Among 100 patients and staff followed for 1 yr, 92-94% did not change their anti-HA status. The prevalence of anti-HA was identical in subjects with past histories of multiple blood transfusions or accidental inoculations with blood-contaminated instruments and in those without such histories. It is concluded that hepatitis A virus rarely if ever spreads by parenteral mechanisms, that there is no epidemiologic evidence confirming the existence of chronic hepatitis A viremic carrier states, and that hemodialysis does not play a significant role in the spread of type A hepatitis.

5873 FECAL EXCRETION OF HEPATITIS A VIRUS IN HUMANS. (Eng.)

Rakela, J.; Mosley, J. W. (Univ. Southern California Sch. Medicine, Los Angeles, CA 90007). *J. Infect. Dis.* 135(6):933-938; 1977.

To define more completely the period of fecal excretion of virus during hepatitis A virus infection, 24 fecal samples from six children with clinical illness were studied during an epidemic of type A hepatitis. Immune electron microscopy revealed that all six patients had detectable virus excretion before or by the time of the first abnormality in serum glutamic-pyruvic transaminase (alanine aminotransferase). Viral excretion reached a peak early and declined to undetectable levels before levels of serum enzyme reached a peak. These data are in accord with epidemiologic evidence that individuals with symptoms and signs of type A hepatitis are unlikely to transmit the infection to others. Immune electron microscopy, may be a better index to the period of communicability than studies of experimental infection in human subjects. This conclusion suggests that precautions against fecal contamination are not usually necessary for hospitalized patients with type A hepatitis.

5874 TRANSMISSION OF NON-A, NON-B HEPATITIS. (Eng.)

Hoofnagle, J. H.; Gerety, R. J.; Tabor, E.; Feinstone, S. M.; Barker, L. F.; Purcell, R. H. (151-F, Veterans Admin. Hosp., 50 Irving St. N.W., Washington, DC 20422). *Ann. Intern. Med.* 87(1):14-20; 1977.

The stored serum samples from six asymptomatic blood donors who were implicated in the transmission of viral hepatitis were reanalyzed using serologic markers for hepatitis B virus and hepatitis A virus infection. The samples had been stored at -20 C for 25 yr. Two of the donor sera were hepatitis B surface antigen (HBsAg)-positive, and both transmitted hepatitis B virus infection to all 30 susceptible recipients (at the time of the original study, 25 yr ago), half of whom showed clinical symptoms. The remaining three infectious donors we HBsAg-negative, yet were icterogenic to 10% to 47% of recipients. Testing of serum samples from these recipients with hepatitis showed no evidence of hep titis B virus or hepatitis A virus infection. This study and other recent evidence suggest that there is a third type of human viral hepatitis—non-A, no hepatitis—that is due to a transmissible agent and may be associated with a chronic carrier state.

5875 PARENTERALLY TRANSMITTED NON-A, NON-B HEP TITIS: AN EPIDEMIC REASSESSED. (Eng.)

Meyers, J. D.; Dienstag, J. L.; Purcell, R. H.; Thomas, E. D.; Holmes, K. K. (U.S. Public Health Se vice Hosp., 1131 14th Ave. South, Seattle, WA 98114 *Ann. Intern. Med.* 87(1):57-59; 1977.

To further study the possible etiologic role of hep titis A and Epstein Barr virus in a nosocomial outbreak of parenterally transmitted hepatitis affect both marrow transplant patients and normal platele donors in an oncology unit, stored sera were reexamined for serologic evidence of hepatitis A or Epstein Barr virus infection. Because of the characteristics of the clinical illness, the incubatio period of 27 days, and the effect of immune serum globulin on the clinical illness, the outbreak was attributed to hepatitis A; there was no serologic evidence of either hepatitis B virus or cytomegalovirus infection. Ten patients and donors had undetectable antibody to hepatitis A (anti-HA) titer before illness and none seroconverted; five person had pre-existent anti-HA titers and showed no furt rise in convalescent sera. The serum of one patie was inevaluable. With the availability of serolog techniques for the diagnosis of both hepatitis A a hepatitis B virus infections, it is clear that mos cases of post-transfusion hepatitis are not due to either of these agents, and short incubation-perio hepatitis can not be assumed to be hepatitis A wit out further investigation.

5876 CLINICAL AND DIAGNOSTIC ASPECTS OF CYTOMEGALOVIRUS-INDUCED HEPATITIS. (Ger.)

Heni, N.; Heissmeyer, H.; Schmitz, H. (Medizinisch Universitatsklinik, Hugstetter Str. 55, 7800 Freiburg, W. Germany). *Dtsch. Med. Wochenschr.* 101 (44):1610-1612; 1976.

The diagnostic parameters for acute cytomegalovir induced infection are reviewed. The parameters i clude a cytomegalic IgM or IgA antibody titer ove 1:64, seroconversion or increase in the complemen binding reaction around the factor 4, and virus isolation from urine. Hepatitis and liver infect in connatal cytomegalovirus infection; symptoms o cytomegalic hepatitis in infants, children, and a ults; and differential diagnosis of the infection as compared to hepatitis B are also reviewed. Me n values of bilirubin maxima of 47.9 μM (28 mg/l), increase in γ-GT of up to 250 U/l, and a decrease seral iron level to an average of 11.6 μM (650 /l) have been established in cytomegalovirus patitis patients.

77 SIGNIFICANCE OF LIVER SIDEROSE EXAMINATION IN ACUTE VIRAL HEPATITIS. (Ser.) Janev, B. (Medical Faculty, Univ., Belgrade, Yugoslavia). *. Arh.* (9):603-613; 1976.

5878 ON DEVELOPMENT OF HYPOPLASTIC ANEMIA IN PATIENTS WITH INFECTIOUS HEPATITIS. (Rus.) Shovkun, A. G.; Tupitsina, L. I.; Ostrovskaya, A. A.; Pidzhakova, S. S.; Proyavkina, A. M. (Dept. Infectious Childhood Diseases, Rostov-on-Don Medical Inst.; USSR). *Vopr. Okhr. Materin. Det.* 22(4):80-81; 1977.

LIVER AND BILIARY TRACT

Chronic Hepatitis

79 MODIFICATION OF PLASMA ALPHA-FETOPROTEIN LEVELS IN PATIENTS WITH PRIOR VIRAL HEPA-TIS. (Ita.) Gaidano, G. P.; Berta, L.; Boccuzzi, ; Angeli, A.; Frajria, R.; Bosio, G. (Istituto di dicina, Interna dell'Universita di Torino, Torino, aly). *Minerva Med.* 67(49):3193-3198; 1976.

asma alpha-fetoprotein (AFP) levels were determined two groups of patients with viral hepatitis. The rst group had had the disease 4-5 months previous-; the second group had had the disease 2-22 yr fore. No one in either group showed any indica-on of relapse or recurrence of the disease. ver function, as measured by SGOT, SGPT, and alka-ne phosphatase activities, was normal in all jects, and there was no indication of bilirub-emia. Hepatitis B antigen assays were negative all subjects. The median AFP value of all sub-cts was 3.75 ng/ml compared to a median of 1.29 /ml in normal subjects. Increased AFP levels be observed in acute viral hepatitis as a re-t of regeneration of necrotic tissue. The nes of liver cells that produce AFP may persist the liver after regeneration is complete, causing elevation of AFP observed in the recovered sub-cts.

30 IMMUNOLOGICAL STUDIES IN PROLONGED AND CHRONIC HEPATITIS. INTEREST IN DIAGNOSIS PROGNOSIS: 100 CASES. (Fre.) Ribet, A.; Nad-ny, M.: Oksman, F.; Frexinos, J. (Clinique des adies de l'Appareil Digestif, CHU de Rangueil, te de Narbonne, F-31054 Toulouse, France). *v. Presse Med.* 5(37):2440-2443; 1976.

immunological status of 100 patients with pro-ged hepatitis (PH), chronic active hepatitis H), and persistent chronic hepatitis (PCH) was luated during the third month of their disease. was generally paired with a normal immunologic dition, except for a frequent increase in gam-lobulins, IgG. The persistence of Australian igen at this stage strongly indicated a transition to a chronic, noncirrhotic hepatitis. ACH could usually be distinguished from PCH by the presence of high IgG levels. It could be found either with or without Australian antigen and/or autoantibodies. Cirrhosis was foreshadowed by a marked increase in IgA and IgM and by high levels of antinuclear and anti-smooth muscle antibodies.

5881 REACTION OF HUMAN SMOOTH MUSCLE AUTOANTIBODY WITH GASTRIC PARIETAL CELLS: A PITFALL IN THE DIAGNOSIS OF PARIETAL CELL AUTOANTIBODY. (Eng.) Ceredig, R.; Toh, B. H. (Monash Univ. Medical Sch., Commercial Rd., Prahran, Melbourne 3181, Australia). *J. Clin. Pathol.* 30(7):666-670; 1977.

Thirteen smooth muscle antibody (SMA) sera obtained from 13 patients with active chronic hepatitis were examined for immunofluorescence reactivity with gastric mucosal cells. Eight sera stained the cytoplasm of gastric parietal cells in a pattern indistinguishable from that obtained with parietal cell autoantibody (PCA). The staining reaction was localized to parietal cells by the demonstration that the same cells stained with both SMA and PCA in double immunofluorescence tests. The SMA staining intensity for parietal cells was weaker than that for smooth muscle. Specificity of the staining reaction for actin was established by the observation that parietal cell staining by SMA was inhibited by serum absorption with skeletal muscle F-actin but not by a microsomal fraction derived from gastric mucosa. Actin may play a role in the process of parietal cell acid secretion.

5882 MORPHOLOGIC ASSOCIATION OF LYMPHOCYTES WITH HEPATOCYTES IN CHRONIC LIVER DISEASE. (Eng.) Kawanishi, H. (Ann Arbor Veterans Admin. Hosp., 2215 Fuller Rd., Ann Arbor, MI 48105). *Arch. Pathol. Lab. Med.* 101(6):286-290; 1977.

The interrelationship between immunologically associated lymphocytes and hepatocytes was examined by light and electron microscopy, using epoxy-resin embedded thick and thin sections of biopsy liver tissues from seven patients with chronic persistent hepatitis (CPH) and nine with chronic active liver disease (CALD). Close apposition of lymphocytes with hepatocytes was classified according to morphologic features produced by surface contact, invagination, direct penetration, and aggregation. Lymphocytes in biopsy specimens from patients with CALD showed these morphologic patterns much more frequently than those from patients with CPH. Single-cell adherence occurred an average of five or more times per 10 blocks in subjects with CALD and only 0-2 times in subjects with CPH; the corresponding frequencies for clustering were 2-4 and 0-1, and for invagination were 1-2 and 0-1. These small, infiltrating lymphocytes established intimate contact with hepatocytes through their multiple-surface projections. Hepatocyte degeneration appeared to occur in association with the structural contact. The morphologic association of lymphocytes with hepatocytes in CALD is consistent with the participation of cell-mediated immune processes.

Alcoholic Liver Disease

395 ALCOHOL CONSUMPTION AND DISEASES OF THE LIVER. (Eng.)

Thaler, H. (Wilhelmins-
tal, Montleartstrasse 37, A-1171 Vienna, Austria).
tr. *Metab.* 21(1/2/3):186-193; 1977.

e development of alcoholic liver diseases is re-
ewed. Alcoholic liver damage is only produced by
nstant alcohol intake. Close dose and time rela-
onships are apparent. For many years, alcoholic
tty liver is the only noticeable alteration. It
completely reversible in 2-4 weeks when ethanol
take is stopped. After about 6 yr of chronic
use, alcoholic hepatitis may develop. Once es-
blished, it progresses within weeks or months to
rrhosis if ethanol intake is not discontinued.
the other hand, alcoholic hepatitis heals under
mplete abstinence from alcohol with unimportant
brosis. After over-indulgence in alcohol over a
riod of 22 yr, there is a 50% probability of cir-
osis, demonstrating that the resistance of the
ver to alcohol varies considerably in different
dividuals. In early stages of alcoholic cirrhosis
e prognosis is good; if these patients observe
mplete abstinence from ethanol, their life expec-
ncy is only slightly different from the average
pulation. The extent of alcohol consumption is
cisive in the development of cirrhosis. New in-
stigations reveal that the susceptibility to al-
hol is different in both sexes. For men the danger
vel appears to be approximately 60 g and for
men around 20 g of 100% alcohol a day. Beyond
ese critical levels the morbidity of cirrhosis
ltiplies almost in geometric progression with in-
easing amounts of ethanol.

96 CLOMIPHENE CITRATE THERAPY IN A PATIENT WITH LAENNEC'S CIRRHOSIS. (Eng.)

Bjork,
T.; Varma, R. R.; Borkowf, H. I. (Milwaukee
nty General Hosp., 8700 W. Wisconsin Ave., Mil-
kee, WI 53226). *Gastroenterology* 72(6):1308-
1; 1977.

case of a patient with advanced Laennec's cir-
sis who was treated with clomiphene citrate is
sented. The patient, a 36-yr-old man, had ab-
ined from alcohol and had stable hepatic function
ts for 1 yr before starting therapy. Prior to
rapy, the cirrhosis was complicated by gyneco-
tia, testicular atrophy, impotence, and loss of
ido. Clomiphene citrate was started at a p.o.
e of 50 mg daily for 4 weeks, with increases in
dose of 50-mg increments at each 4-week interval
il the daily dose totalled 200 mg. At the low-
daily dose, luteinizing hormone and endogenous
tosterone levels were maximally elevated (87.5
/ml and >1.32 μg/dl, resp.). Follicle stim-
ting hormone was maximally elevated with the 100
dose (81.1 mIU/ml), and the elevation of total
rogen level was not affected by increasing the
e (it remained between 20.7 and 29.0 until 2
ths after therapy was discontinued). The total
tosterone level remained elevated 4 months after therapy was stopped, and luteinizing hormone remained elevated for 3 months. The androgen to estrogen ratio was unchanged with clomiphene citrate, but increased after completion of the therapy at 6 months. Prolactin levels were normal before and after therapy. During treatment, increase in testicular size was noted with resolution of impotence and improvement of libido that continued for 6 months after cessation of therapy. The gynecomastia remained unchanged despite the increased serum testosterone. An ejaculate for semen analysis, unobtainable before clomiphene citrate, was obtained after completion of therapy; it showed a normal volume and sperm count but poor motility with increase in abnormal and immature forms. There were no side-effects resulting from therapy. The patient relapsed, with regard to loss of libido and impotence, 8 months after therapy was discontinued. The data suggest that endocrine abnormalities in cirrhosis may improve at least transiently with clomiphene citrate therapy.

5897 EPIDEMIOLOGY OF FATTY DEGENERATION OF THE LIVER. (Ger.)

Buttner, W.; Bauch, K. (Bezirkskrankenhaus, Klinikum am Kuchwald, DDR-90 Karl-Marx-Stadt, Burgerstr. 2, E. Germany). *Dtsch. Gesundheitsw.* 32(19):887-890; 1977.

The occurrence of fatty degeneration of the liver in healthy subjects and patients of different age categories was determined with the aid of 3,760 liver biopsies and 338 liver specimens obtained at autopsy. The patients were classified into various categories including recently discovered untreated diabetics (263 biopsies), treated diabetics (432), apparently healthy persons (3,065), and those that died suddenly of unnatural causes (338 suicides and accidents). According to histological criteria established by Wildhirt, fatty degeneration of the liver was found in 38.8% of the recently discovered untreated diabetics, 19.6% of the treated diabetics, 9.6% of the apparently healthy subjects, and in 2.7% of the postmortem specimens. The occurrence of fatty degeneration of the liver was most frequently found between the ages of 55-65 yr, whereas it was lowest between 40-55 yr of age; alcohol was the chief cause of degeneration in male postmortem specimens, and fatty liver was also predominant in men up to 45 yr among the apparently healthy subjects. Fatty liver occurred more frequently in women past 45 yr of age, and overeating and obesity played a role in this condition in these latter individuals.

5898 ALCOHOL AND HYPERTENSION. (Eng.)

Beevers, D. G. (Western Infirmary, Glasgow G11 6NT, Scotland). *Lancet* 2(8029):114-115; 1977.

Because of the suggestion that there could be an association between alcohol intake, liver dysfunction, and raised blood pressure, liver function data were compared in 158 unselected hypertensives and 105 normotensives aged 45-64 yr. SGOT and SGPT concentrations were higher in male hypertensive patients than in normotensive men; 8.7% of the hypertensive men had elevated SGPT levels (>21 U/1) in comparison with 3.8% of the normotensive men ($p<0.01$), and the respective percentages for SGOT elevation were 4.1 and 2.0 ($p<0.02$). In female hypertensives, only SGOT distributions were significantly different from those in normotensive women (6.3% versus 2.0%, resp., $p<0.05$), although raised concentrations of SGOT and SGPT were more common in the hypertensive patients. SGPT tended to be higher in heavier drinkers (41.0 ± 10.1 U/1 in men, 32.3 U/1 in women) than in occasional drinkers (29.8 ± 2.3 U/1 in men, 22.8 ± 3.7 U/1 in women) or non-drinkers (27.4 ± 4.8 U/1 in men, 19.7 ± 2.0 U/1 in women); these differences were not statistically significant. The findings support the observation of an association between increased alcohol intake and high blood pressure and between liver damage and high blood pressure.

LIVER AND BILIARY TRACT

Cirrhosis

5901 PATHOLOGIC ASPECTS OF CIRRHOSIS: A REVIEW. (Eng.) Popper, H. (Mount Sinai Sch. Medicine, Fifth Ave. and 100th St., New York, NY 10029). *Am. J. Pathol.* 87(1):228-264; 1977.

Pathologic aspects of liver cirrhosis are reviewed. Although cirrhosis is characterized conventionally by a nodular parenchyma and widespread fibrosis with hepatocellular necrosis sometimes listed as a third component, cirrhosis is better described as the result of abnormal reconstruction of the preexisting lobular architecture. The following criteria indicate cirrhosis (with decreasing certainty): nodules surrounded by septa with or without portal and central canals (in fibrosis, a parenchymal portion near portal tracts may sometimes appear round), hepatic vein tributaries in contact with septa, connective tissue septa linking central with portal canals (particularly when bent or zigzag), fragmentation of specimens into round pieces surrounded in more than half of their circumference by thin layers of connective tissue, and irregularity of architecture including circumscribed variations in hepatocyte size and cell plate thickness, abnormal spacing of vascular channels, an excess of hepatic vein tributaries over portal tracts (especially if the latter are small) and, in adults, a paucity of centrolobular lipofuscin pigment in newly formed hepatocytes. Alteration of hepatic circulation is the key feature of cirrhosis and is also the main target of therapy in cirrhosis. Additional features that accompany, or are caused by, the altered hepatic circulation include: reduced functional mass of hepatic parenchyma, increased hepatic lymph flow, alteration of bile flow, and excess iron storage in periportal hepatocytes. Although cirrhosis is conventionally considered as an irreversible scar stage, collagen fiber turnove suggests a possible regression of septa. Thinnin and even disappearance of septa and relobulation nodules has been observed in experimental studies In man, regression of cirrhosis of the iron overload type has been described.

5902 DOES INTRA-ARTERIAL VASOPRESSIN CONTROL GASTROINTESTINAL BLEEDING IN CIRRHOTIC PATIENTS? (Eng.) Mackenzie, R. L.; Bury, K. D.; Provan, J. L.; St. Louis, E.; Marcon, N. (Wellesle Hosp., 160 Wellesley St. E., Toronto, Ontario, M4 IJ3, Canada). *Can. J. Surg.* 20(4):356-359; 1977.

The use of continuous intra-arterial infusion of vasopressin in the control of gastrointestinal bleeding was assessed in 24 cirrhotic patients wi

eeding. In all patients, the bleeding was local-
ed to esophageal varices or gastric erosions, or
th. Seventeen (71%) patients initially responded
vasopressin. Five patients stopped bleeding;
o of these survived and three died of liver fail-
e. In 12 patients the bleeding stopped or par-
al control of bleeding was achieved, but 11 of
em had further severe hemorrhage on one or more
casions; only 2 of the 12 survived. Seven pa-
ents did not respond to vasopressin; six of them
ed. The overall mortality was 79%. The data
ggest that the administration of intra-arterial
sopressin brings about temporary control of bleed-
g in some cirrhotic patients with gastrointestinal
morrhage but that current survival rates are poor.

03 DEMECLOCYCLINE: A NEW TREATMENT FOR WATER AND SODIUM RETENTION OF CIRRHOSES AND RE-
ACTORY ASCITES? (Fre.) Poupon, R.; Gustot, P.;
rnis, F. (Service d'Hepato-Gastroenterologie,
pital Saint-Antoine, 184, rue du Faubourg Saint-
toine, F 75571 Paris Cedex 12, France). *Nouv.
esse Med.* 5(31):1993-1994; 1976.

ve cirrhotic patients with refractory ascites and
ema were treated with demeclocycline (1,200 mg/
y) for at least 8 days. Urine output increased
om 300-900 ml/day to 1,800-2,700 ml/day. A di-
tion hyponatremia, which was present in three of
ve patients, was corrected, with sodium values
sing from 127-131 mEq/l to 135-149 mEq/l. Sodium
cretion rose from 0-10 mEq/day to 40-145 mEq/day.
e ascites and edema cleared up in three of five pa-
ents by the prolonged use of demeclocycline only,
thout any other treatment. These results confirm
e action of demeclocycline on abnormal antidiu-
tic hormone activity and reveal its natruretic
fect. It should be used only in patients with
rmal or elevated plasma volumes and with normal
al function.

04 PRE- AND POSTOPERATIVE EEG PROFILES IN PATIENTS WITH CIRRHOSIS OF THE LIVER
ER SHUNT OPERATION. (Ger.) Lanzinger-Rossnagel,
Christian, W.; Kommerell, B. (Medizinische Uni-
sitatsklinik, 6900 Heidelberg 1, Bergheimerstr.
W. Germany). *Dtsch. Med. Wochenschr.* 102(19):
-731; 1977.

readings were performed 1-3 months before and
to 5 yr after shunt operations in 27 patients
ed 16-69 yr) with liver cirrhosis and esophageal
ices, mostly of alcoholic etiology. Twenty pa-
nts had therapeutic shunts (direct portacaval
stomosis); indirect shunts were performed in
atients. Of the 27 patients, 14 already had
hological EEG changes (grade II-V) prior to
nt operation indicating hepatic encephalopathy.
toperatively, 16 of the 27 patients had patho-
ical EEG recordings. Generalized steep poten-
ls were seen frequently. Only four preoperatively
mal patients had cerebral dysfunction (enceph-
pathy) after the procedures. In two patients,
preoperative abnormal EEG worsened and persisted
to 4 wk postoperatively. The bioelectrical
disturbance manifested itself only 2-4 yr later in three patients. However, the basic disease (liver cirrhosis) can cause progressive encephalopathy. Of the 27 patients, 10 died within 2 months to 3.5 yr after the shunt operation; 5 patients had normal EEG findings preoperatively, whereas 5 had pathological grade II-V curves. The latter five died in hepatic coma, whereas three of the former five patients died of other diseases (prostatic carcinoma, cerebral hemorrhage, and acute dystrophic attack from liver cirrhosis). The cause of death was unknown in two patients. The results indicate that no improvement in the EEG occurs in patients with preoperative encephalopathy following shunt operation.

5905 EXPERIMENTAL RESEARCH ON ARTIFICIALLY INDUCED ANTIBODY IMMUNITY IN NORMAL SUBJECTS AND PATIENTS WITH CIRRHOSIS OF THE LIVER.

(Ita.) Zanacchi, G.; Bianchini, G.; Tentoni, M. (Istituti Ospitaliere di Cremona, II Divisione Medica, Cremona, Italy). *Minerva Med.* 68(9):587-598; 1977.

The immune response was measured in 20 patients with cirrhosis of the liver and in 5 normal controls given five injections of tetanus toxin at weekly intervals, and in 13 cirrhotic patients and 12 controls given a single injection of typhoid vaccine. Antibody (Ab) titer to tetanus toxoid was measured by passive hemagglutination; Ab titer to typhoid vaccine was measured by macroagglutination. Immunoglobulins G, A, and M (IgG, IgA, IgM) were measured by a radial immunodiffusion. There was no difference in Ab response to tetanus toxoid between cirrhotic patients and normal controls. IgM and IgA response after tetanus toxoid was higher in cirrhotic patients. Cirrhotic patients showed a minimal increase in IgG and IgA levels and a decrease in IgM levels following typhoid vaccine, while normal subjects showed a slight increase in IgG levels only. Antibody response to typhoid vaccine was significantly higher in cirrhotic patients, however. There was an increase in plasma cells and lymphocytes in the bone marrow of cirrhotic patients after typhoid vaccine administration. Increased IgG production in cirrhotics is seen as a generalized increased Ab response not related to immune pathogenesis. The liver may regulate immune response in some manner and this regulatory mechanism may be "turned off" during cirrhosis.

5906 IRON CONTAINING NUCLEAR INCLUSIONS IN HUMAN PIGMENTARY CIRRHOSIS.

(Ger.) Altmann, H. W. (Pathologisches Institut, Universitat Wurzburg, D-8700 Wurzburg, W. Germany). *Virchows Arch.* [*Cell Pathol.*] 23(4):277-290; 1977.

Iron-containing nuclear inclusions were studied in biopsy specimens from a 69-yr-old man with pigmentary cirrhosis. Nuclear inclusions of cytoplasmic material containing degenerated and faintly stained hemosiderin granules were observed. Finely fibrillar or granular proteinaceous material, stainable by the Prussian blue reaction, were sometimes observed lying between the chromatin strands or occupying the whole nucleus and displacing the chromatin to the nuclear envelope ("margination of chromatin"). This material condensed into homogeneous masses and formed hexagonal yellowish-brown crystals with a diameter of up to 14 μ. The nuclear envelope and the marginated chromatin were eventually destroyed, and the crystals thus occurred free in the cytoplasm. The cytoplasm was eventually destroyed and ingested by the Kupffer cells. The intranuclear deposits of iron-containing protein were interpreted to be ferritin aggregates. It is proposed that ferritin molecules, built up in the cytoplasm, enter the nucleus via the pores of the nuclear envelope. Such an event signals a cytopathologic reaction and gives rise to cell shrinking and cell death.

5907 FAMILIAL HEMOCHROMATOSIS: PHYSIOLOGIC STUDIES IN THE PRECIRRHOTIC STAGE OF THE DISEASE. (Eng.) Feller, E. R.; Pont, A.; Wands, J. R.; Carter, E. A.; Foster, G.; Kourides, I. A.; *et al.* (Massachusetts General Hosp., Boston, MA 02114). *N. Engl. J. Med.* 296(25):1422-1426; 1977.

Twelve members of a family with precirrhotic hemochromatosis were studied to define the physiologic abnormalities in the asymptomatic phase of the disease. Six of 12 had increased iron stores; the mode of inheritance was consistent with an autosomal dominant trait. Serum ferritin levels were no more predictive of tissue iron levels than measurements of serum iron, transferrin saturation, or chelatable iron excretion. In three affected family members, intestinal iron content was normal. Liver proline hydroxylase activity and urinary hydroxyproline excretion did not correlate with tissue iron content, suggesting that, in addition to the possible role of tissue iron, hepatic fibrosis may involve other factors. "Borderline diabetes mellitus" was present in three affected family members, but extensive studies revealed that pituitary dysfunction is uncommon in early hemochromatosis. Increased levels of liver iron proved to be the most reliable marker for the disease.

5908 PREGNANCY IN LIVER CIRRHOSIS AND/OR PORTAL HYPERTENSION. (Eng.) Cheng, Y. S. (Memorial Medical Center, P.O. Box 6688, Station C, Savannah, GA 31405). *Am. J. Obstet. Gynecol* 128(7):812-822; 1977.

Clinical features of pregnancy in women with liver cirrhosis and/or portal hypertension are reviewed. Termination of pregnancy is seldom indicated in a woman with compensated cirrhosis or a young woman with extrahepatic venous obstruction. However, the risk of spontaneous abortion is increased in cirrhotic women without shunt even if there is no deterioration of liver function. The risk of bleeding from esophageal varices or of deterioration of liver function is usually unpredictable. Shunt surgery can be done with relatively little effect on both the mother and the fetus if conservative measurements fail to control the hematemesis. Vaginal delivery can be anticipated in most women, and cesarean section should be reserved for obstetric indications. The risk of postpartum hemorrhage is greatly increased, particularly in patients with previous shunt surgery. Perinatal loss is high because of the increased rate of premature delivery and stillbirth. Maternal prognosis is grave in women with cirrhosis.

5909 SPONTANEOUS BLOOD SHUNTS IN CIRRHOSIS. (Rus.) Ivkov, V. G. (Municipal Clinical Hosp. #31, Moscow, USSR). *Klin. Med.* 55(4):20-24; 1977.

See also, 5396, 5397, 5800, 5815, 5816, 5858, 5884, 5892, 5893, 5894.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

5910 BILE LEAKAGE FOLLOWING PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY WITH THE CHIBA NEEDLE. (Eng.) Juler, G. L.; Conroy, R. M.; Fuelleman, R. W. (5901 E. 7th St., Long Beach, CA 90822). *Arch. Surg.* 112(8):954-958; 1977.

Experience with the Chiba needle in percutaneous transhepatic cholangiography (PTC) for jaundice of undetermined etiology in 30 patients is presented. Successful visualization of the biliary ductal system was accomplished in 26 patients; 2 of 6 patients with normal biliary systems had ducts visualized, and the ducts were visualized in the 24 patients (100%) with obstruction. Bile leakage of 50 to 500 ml (average, 200 ml) was observed at laparotomy or autopsy in 12 patients (40%), 9 (30%) of whom had symptoms of peritonitis. Six (20%) of these were transient and three (10%) progressed to an acute abdomen. Bacteremia occurred in seven patients (23.3%); in three (10%) it progressed to septic shock, with one death. There were no complications in patients with nonobstructed ducts. This study suggests that PTC with the Chiba needle has little advantage over the larger sheathed needles, and surgical standby is indicated in suspected cases of obstructive jaundice.

5911 INTRAVENOUS CHOLANGIO-CYSTOGRAPHY DURING CHILDHOOD. (Ger.) Fahr, K.; Opperman, H. C.; Willich, E. (Universitats-Kinderklinik, Im Neuenheimer Feld, 150, 6900 Heidelberg 1, W. Germany). *Fortschr. Roentgenstr.* 126(6):571-576; 1977.

Intravenous cholangiography was performed in 25 children (aged 2-15 yr) by injection (10 patients) or infusion (15) for epigastric complaints (7), icterus of unknown origin (3), epigastric tumor (3), round cell anemia (2), increased transaminase levels (2), occlusive icterus (1), suspicion of cholelithiasis (1), and liver calcification (1). Four control tests were also performed. The contrast media used (Biligram, 17% and 35% solutions) for infusion ranged from 0.8 to 1.6 ml/kg and for injection from 0.4 to 0.8 ml/kg, depending upon the age of the child. Overall, both methods provided good x-ray pictures of the biliary tree and gallbladder, and films were taken 30, 60, and 90 min after end of the injection and 40 min after a fatty meal. In only six cases could no images be seen. No pathological findings were noted in 8 of 15 patients given infusion. A segmental bile duct dilatation was diagnosed in two, colon fistula in one, and calculi in another child. Of the 10 patients given Biligram injection, segmental bile duct dilatation was diagnosed in a 3-yr-old child; no pathological findings were found in the other 9. Tolerance to both procedures was good. One patient with a known orthostasis syndrome developed collapse symptoms 3 hr after start of the trial, but this was not attributed to the contrast medium. No changes in SGOT, SGPT, LDH, or alkaline phosphatase levels were noted. Contrast medium was found in the gastrointestinal tract in 13 cases, which indicated that at least part of the i.v. injected agent had already passed into the intestines with the bile. Thus, this finding can also be used as a diagnostic indication of a hyperkinesis of the bile ducts and can exclude cholestasis.

5912 THE EFFECT OF CARBACHOL ON THE GALLBLADDER IN BLACK AND WHITE SUBJECTS. (Eng.) Drew, S. I.; Bayever, E.; Levy, J. I. (Dept. Surgery, Univ. California, Los Angeles, CA). *S. Afr. Med. J.* 51(21):739-740; 1977.

The effect of carbachol on gallbladder emptying was compared in 24 healthy Negro and 24 healthy Caucasian subjects. Cholecystography revealed no significant gallbladder contraction following the s.c. injection of carbachol (0.3, 0.6, 1.3, or 3.3 μg/kg) in the Caucasian subjects; no significant contraction was seen in one white patient after the injection of 3.6 μg/kg carbachol. Negro subjects showed a marked reduction in gallbladder size after the 1.3-μg dose ($p<0.05$), but not at any of the other three dose levels. No difference in gallbladder contractility was found between men and women, nor did gallbladder response appear to be related to oral contraceptive use. The greater contractility of the gallbladder in Negroes may account for the lower incidence of cholelithiasis in this population.

5913 THE SIGNIFICANCE OF CONJUGATED PHENOBUTIODIL (BILIODYL) IN THE INTESTINE IN THE ABSENCE OF GALLBLADDER OPACIFICATION: A PRELIMINARY ASSESSMENT. (Eng.) Calder, J. F. (Kenyatta Natl. Hosp., P.O. Box 30588, Nairobi, Kenya). *Clin. Radiol.* 28(3):299-300; 1977.

The significance of conjugated phenobutiodil in the intestine in the absence of gallbladder opacification was assessed in 41 patients. The gallbladders of these patients failed to opacify after two 3-g doses of the contrast medium. Thirty-four of these patients had conjugated phenobutiodil in the intestine, as evidenced by a 35 x 35 cm abdominal film. Thirty-three of these patients were shown by surgery or i.v. cholangiography to have gallbladder disease. The remaining patient appeared to have a normal gallbladder at operative cholangiography, and her symptoms were attributed to a duodenal ulcer. These findings indicate that the presence of conjugated contrast medium in the intestine in the absence of gallbladder filling strongly suggests the presence of gallbladder lesions.

5914 CONGENITAL DISEASES OF THE GALLBLADDER AND BILE DUCTS. (Eng.) Hatfield, P. M.; Scholz, F. J.; Wise, R. E. (605 Commonwealth Ave., Boston, MA 02215). *Semin. Roentgenol.* 11(4): 235-243; 1976.

The various types of cystic and noncystic diseases of the bile ducts are reviewed. Among the cystic diseases of the bile ducts, choledochal cyst (rare and difficult to diagnose), choledochocele (diverticulum of the common bile duct, diagnosis by cholangiography), solitary (nonparasitic) liver cyst (rare, diagnosed by a ^{99m}Tc-sulfur colloid liver scan, ultrasound, or computerized tomography and intravenous cholangiography), cystadenoma (1.5 to 25 cm in diameter), and polycystic disease of the liver are discussed. Among the noncystic diseases of the bile ducts, ductal ectasia in two forms (Caroli disease and congenital hepatic fibrosis with ductal ectasia, biliary atresia, and congenital strictures) are described. The majority of clinically significant congenital variations in the gallbladder (except choristoma) were reported in an earlier paper.

5915 THE DIAGNOSIS OF CYSTIC MALFORMATIONS OF THE BILIARY TREE DURING CHILDHOOD. (Ger.) Bliesener, J. A.; Wieners, H. (Kinderklinik/Rontgen-Abt., Amsterdamer Strasse 59, 5000 Koln 60, W. Germany). *Fortschr. Roentgenstr.* 126(6):577-580; 1977.

Cystic malformations of the biliary tree were diagnosed in a 22-month-old girl with obstructive jaundice by percutaneous transhepatic cholangiography

(PCH). The patient presented with icterus, right-sided epigastric pain, and a slightly enlarged liver. After 4 weeks, the patient's alkaline phosphatase (AP) level rose to 437 mU/ml, but no abnormalities were found by x-ray examination. Upon hospitalization, the AP, LDH, and total bilirubin levels were 3,810 mU/ml, 239 mU/ml, and 3.1 mg%, resp. A PCH was decided upon; well-defined dilation of the intra- and extrahepatic bile ducts was found, with septal-type stenoses at the confluens hepaticum. Operation revealed a high grade cystic dilation of the choledochus with bile grit and a stone; additional stenoses of the papillary region were also seen. A Roux-Y-Plastic procedure was performed, and the postoperative course was without complications. The AP level dropped, and total bilirubin decreased to 0.27 mg%. An x-ray follow-up revealed a decrease in the dilation of the bile ducts.

5916 PROSTAGLANDINS IN CHRONIC CHOLECYSTITIS.

(Eng.) Wood, J. R.; Stamford, I. F. (King's Coll. Hosp. Medical Sch., London SE5 8RX, England). *Prostaglandins* 13(1):97-106; 1977.

Prostaglandin (PG)-like material was extracted from the mucosa and muscle wall of 16 chronically inflamed human gallbladders. Basal PG levels obtained by homogenizing mucosa and muscle wall samples in acid-ethanol (AE) or in Krebs solution containing 10 μg/ml indomethacin (KIN) were similar, ranging from less than 1 up to 40 ng PGE_2 equivalents/g fresh tissue (AE) and from less than 1 up to 57 ng PGE_2 equivalents/g (KIN) in mucosa homogenates. These mean basal levels were 11.7 times higher than those in muscle wall homogenates ($p<0.0025$). More PG-like material was extracted from homogenates in Krebs solution without indomethacin, with the levels in the mucosa being 3.4-4.6 times basal levels (AE and KIN, resp.) and the levels in the muscle wall being 3.1 and 4.3 times basal levels (AE and KIN, resp.). The synthesized PG levels assayed in homogenates in Krebs solution without indomethacin were 12.7 times higher in the mucosa than in the muscle wall. Mucosal PG levels were higher in gallbladders with multiple gallstones (18-380 ng PGE_2 equivalents/g) than in gallbladders with a solitary stone (less than 1 up to 20 ng PGE_2 equivalents/g). Chromatography of mucosal extracts showed substances indistinguishable from primary PGE and PGF compounds together with a PGD_2-like component. When gallbladders were categorized according to pre-operative cholecystogram results, levels of mucosal PG-like material were not significantly different in the visualized and non-visualized groups. The above results show that both mucosa and muscle wall from chronically inflamed human gallbladders can synthesize PG-like material and that indomethacin inhibits this synthesis. PG levels did not correlate with the extent of the chronic inflammatory cell infiltrate.

5917 ALIATHIASIC CHOLECYSTOPATHIES: CLINICAL, DIAGNOSTIC AND THERAPEUTIC ASPECTS.

(Ita.) Spagliardi, E.; Guarda, P.; Levi, M.; Palombo, D.; Parini, U.; Sblendorio, L. (Divisione di Chirurgia Generale, Ospedale Regionale, Aosta, Italy). *Minerva Med.* 67(30):1935-1947; 1976.

The clinical, diagnostic, and therapeutic aspects of aliathiasic cholecystopathies are reported. The frequency of cholecystopathy is discussed, and the various disease forms are classified into diffuse and localized dyskinesias. The diffuse forms of the disease may be treated if the patient elects to do so. The localized disease should be treated by surgical intervention. Cholecytosis is also discussed, and diagnostic techniques and therapy for al forms of the disease are presented.

5918 THE RESULTS OF CHOLEDOCHODUODENAL ANASTOMOSES IN BILIARY LITHIASIS.

(Fre.) Maillet, P.; Chabal, J.; Boulez, J.; Barbier, B.; Sauma, A.; Baulieux, J. (Hopital de la Croix-Rousse, 69004 Lyon, France). *Ann. Chir.* 31(3):229-239; 1977.

A series of 148 patients were treated for biliary lithiasis with choledochoduodenal anastomoses (CDS) of which 105 were primary interventions and 43 secondary. The postoperative mortality was 4%. Long-term results were evaluated in 112 patients. Moderate to severe cholangitis recurred in only 5% of them, and it usually responded to medical treatment. Pathogenetically, the cholangitis was due to stasis, not to reflux. A reintervention was necessary in four cases; of these, there was one case of stenosis of the anastomosis, and three cases of recurrent lithiasis. The prognosis was generally poorer when intrahepatic lithiasis or acute inflammatory conditions were present. Results were good to excellent in 98.7% of primary CDS and in 82.3% of secondary CDS. These findings confirm the value of CDS; its replacement by other types of anastomoses does not seem justified.

5919 IN VITRO STUDIES OF GALLSTONE DISSOLUTION USING BILE SALT SOLUTIONS AND HEPARINIZED SALINE.

(Eng.) Hardie, I. R.; Green, M. K.; Burnett, W.; Wall, D. R.; Hall-Brown, A. (Dept. Surgery, Univ. Queensland, Brisbane, Queensland, Australia). *Br. J. Surg.* 64(8):572-576; 1977.

A controlled *in vitro* study of gallstone dissolution was carried out using a model designed to simulate the *in vivo* situation in the bile ducts. Sodium taurocholate (200 mM), sodium cholate (200 mM), heparinized saline (100,000 U/1), and physiological saline (0.9%) were infused for 10 days over 81 stones from 32 patients, and changes in weight and structure were recorded. The bile salt solutions caused weight loss in 81.5 and 85.7% of the stones treated, but the two saline solutions caused weight gains in 74.5 and 88%, resp. Fragmentation occurred in 18.5% of stones treated with sodium taurocholate, in 25% of those treated with sodium cholate, and in 11.8% of those treated with heparinized saline. Small stones lost a lower absolute amount of weight than large stones, but this represented a greater proportion of their initial weight. These investigations confirm the advantages of a dynamic *in vitro* model to study gallstone dissolution. Bile salt solutions infused into the bile ducts may clear retained stones by causing reduction in stone weight or fragmentation or both, but heparinized saline appears to be unsuitable for gallstone dissolution. Larger stones may require longer periods of infusion.

5920 THE EFFECT OF SOLVENT FLOW AND SOLVENT CONCENTRATION ON GALLSTONE DISSOLUTION IN VITRO. (Eng.) Motson, R. W.; Way, L. W.; Wong, A. (Veterans Admin. Hosp., San Francisco, CA 94121). *J. Surg. Res.* 22(3):287-293; 1977.

Solutions of bile acids alone, bile acids in combination with lecithin and heparin, and heparin alone were evaluated *in vitro* as cholesterol gallstone solvents in stagnant and flowing systems. Four stones, one from each of four patients, were exposed as a group to each test condition. Under flowing conditions, the solvent solution was continuously recycled at a rate of 20 ml/hr. Under both stagnant and flowing solution conditions, the rate of stone dissolution increased as the bile acid concentration was increased. Under flowing conditions, however, the rate of dissolution for each concentration of each bile acid solution was 5-30% greater than with the same solution without flow. After 2 weeks of exposure, 89% of the aggregate weight of the stones was dissolved by stagnant deoxycholic acid (150 mM) as compared with a 62% dissolution by stagnant (150 mM) cholic acid. In the same solutions with flow, deoxycholic acid dissolved 94% and cholic acid dissolved 92% of the stone weight. Thus, flow eliminated the difference between cholic and deoxycholic acid at the 150 mM concentration. Flow did little to increase dissolution by 100 mM cholate. The greatest effect of flow was seen at 150 and 200 mM concentrations of cholate. Flowing 150 mM cholic acid was equally as effective as the 200 mM concentration, with percentages of aggregate stone weight dissolution ranging from 66 to 98% at 150 mM and 76 to 99% at 200 mM cholic acid. Flow did not substantially change the dissolution rates by either 100 or 150 mM of deoxycholic acid. Heparin had no effect either alone or in combination with cholic acid, and lecithin did not enhance the rate of dissolution produced by cholic acid.

5921 EFFECT OF GALLSTONE-DISSOLUTION THERAPY ON HUMAN LIVER STRUCTURE. (Eng.) Bateson, M. C.; Hopwood, D.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee DD1 9SY, Scotland). *Am. J. Dig. Dis.* 22(4):293-299; 1977.

Liver biopsies were performed before and after 6-8 months of gallstone dissolution therapy with chenodeoxycholic acid (750 mg/day, p.o.) in six patients with gallstones. The only consistent change observed by light microscopy was an increase in the lipofuscin in five of six patients. Electron microscopy of hepatocytes showed consistent increases in lipid droplets and residual bodies after treatment. A slight increase in smooth endoplasmic reticulum, patchy loss of microvilli, and an accumulation of debris in the biliary epithelium were also observed. There was a significant increase in sinusoidal lipocytes or Ito cells after treatment, with the mean volume density (x 10^4) before treatment being 12.6 ± 2.16 and after treatment being 22.0 ± 3.16 ($p<0.001$). These six patients were representative of a group of 20 patients in whom serum liver function tests were followed monthly for at least 6 months. In these patients, the only significant change in blood tests was a modest rise in the aspartate aminotransferase level, which at 6 months after therapy (23.5 ± 8.2 IU) was statistically significant ($p<0.05$) in comparison with the pretreatment level (17.7 ± 3.7 IU). There was a trend towards a decline in both γ-glutamyl transpeptidase and elevated serum triglyceride levels, but the significance of these effects is not clear.

5922 CRITERIA FOR SELECTION OF PATIENTS FOR MEDICAL TREATMENT (CHENODEOXYCHOLIC ACID THERAPY) OF GALLSTONES. (Eng.) Bruusgaard, A.; Malver, E.; Pedersen, L. R.; Schlichting, P.; Sylvest, J. (Medical Dept. B, Frederiksberg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(1):97-102; 1977.

Criteria were investigated for the selection of gallstone patients suitable for chenodeoxycholic acid therapy, i.e., those with cholesterol stones. Gallstone composition studies on 24 consecutive patients admitted for surgery because of gallstones revealed that 17 patients had cholesterol-type gallstones (stones containing more than 50% cholesterol). In 16 of the 17 patients with cholesterol gallstones, the cholesterol saturation index of the bile was above 1.00, while this was also the case in 3/7 patients with non-cholesterol stones. Radiological examination disclosed radiolucent stones in all 17 patients with cholesterol stones and in 3/7 patients with non-cholesterol stones. In 2/3 patients with non-cholesterol stones of the radiolucent type, the cholesterol saturation index of the bile was below 1.00, and in the third patient the index was only slightly elevated (1.16). Thus, by combining the results of radiography and the cholesterol saturation index of the bile, only one patient was incorrectly classified as belonging to the cholesterol stone group, and incorrect exclusion of patients from the cholesterol stone group occurred in only one instance. Although the determination of the lipid composition in bile can only be performed in duodenal aspirate when patients are being selected for medical treatment of gallstones, a comparison of the cholesterol saturation indices in gallbladder bile and duodenal bile in seven patients indicated that in no instance were the indices divergent with respect to the demonstration of normal or abnormal bile (index below or above 1.00). It is concluded that radiolucency of the stones and a cholesterol saturation index in duodenal bile of above 1.00 are fairly reliable criteria for the selection of patients for dissolution therapy with chenodeoxycholic acid.

5923 BREAKING UP RESIDUAL GALLSTONES WITH AN ULTRASONIC DRILL. (Eng.) Davies, H.; Bean, W.; Barnes, F. S. (Univ. Colorado Medical

Center, 4200 E. 9th Ave., Denver, CO 80220). *Lancet* 2(8032):298-299; 1977.

The use of an ultrasonic drill to break up residual gallstones is reported. The patient, a 69-yr-old man, initially underwent cholecystectomy, at which time a size 14 T-tube was left *in situ*. Cholangiography performed through the T-tube 1 month after the operation showed a large stone in the hepatic duct. The stone was mobile and did not obstruct biliary flow. At 3.5 months after the initial operation, a catheter containing a 5-cm basket was passed into the biliary tree under fluoroscopic control. Once the basket extruded beyond the tip of the catheter, the stone was readily trapped in it, and the flexible shaft of the ultrasonic drill was introduced through the lumen of the basket-shaft. The stone broke up, and one 8-mm fragment remained in the duct; this was readily removed with the basket 2 days later. Repeat T-tube cholangiography showed a normal postoperative biliary tree, and the patient is well.

5924 GALLSTONE ILEUS REVEALED BY ENDOSCOPY. (Eng.) Tauris, P. (Silkeborg Centralsygehus, DK-8600 Solkeborg, Denmark). *Endoscopy* 9(2):104-106; 1977.

The case of an 85-yr-old woman with gallstone ileus is presented. The patient presented with epigastric pain, vomiting, and dehydration. Radiological examination revealed gas-fluid levels in the ascending colon but no signs of calculi. Two stones were visualized in the duodenum during panendoscopy. At laparotomy, the stones were manipulated from the duodenum to the stomach, where they were removed through a small gastrotomy. This is the first known case of gallstone ileus that has been diagnosed by direct visualization during endoscopy.

5925 A CRITICAL ANALYSIS OF THE VALUE OF LAPAROSCOPY IN 100 CASES OF CHOLESTATIC ICTERUS. (Fre.) Chousterman, M.; Chaput, J. C.; Buffet, C.; Gueroult, N.; Etienne, J. P. (Hopital A.-Beclere, 157 rue de la Porte-de-Trivaux, 92141 Clamart, France). *Gastroenterol. Clin. Biol.* 1(4): 319-330; 1977.

The diagnostic value of laparoscopy was evaluated in a retrospective study of 100 patients with cholestatic icterus of confirmed etiology. Intrahepatic cholestasis was generally associated with a normal gallbladder (26/28 patients) and a liver that appeared irregular (8/45), nodular (7/43), or tumoral (42/45). Extrahepatic cholestasis was implied when the liver was a uniform or mottled green (48/53) and the gallbladder was distended (31/34) or inflamed and/or lithic (10/12). The level of cholestasis was correctly determined in 81% of patients, misdiagnosed in 6%, and undetermined in 13%. Laparoscopy was especially useful in diagnosing cancer of the liver or pancreas, cholestatic hepatitis, lithic icterus, and alcoholic hepatopathies, which together accounted for 77% of all cases. It is a valuable diagnostic tool and should be performed first before a retrograde cholangiographic endoscopy or other procedure are attempted.

5926 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATICOGRAPHY (ERCP) IN OBSTRUCTIVE JAUNDICE CAUSED BY METASTATIC TESTICULAR TERATOMA. (Eng.) Rentsch, I.; Gartner, U.; Muller, P.; Kerk, L. (Krankenhaus Sebaldsbruck, Saarburger Strasse 56, 2800 Bremen 44, W. Germany). *Endoscopy* 9(2):101-103; 1977.

The case of a 28-yr-old man with obstructive jaundice caused by a metastatic testicular teratoma is presented. The patient presented with back ache, upper abdominal pain, anorexia, weight loss, and a palpable abdominal tumor. He then developed rapidly progressing icterus and elevated liver enzyme levels. The results of an upper gastrointestinal series and i.v. urography suggested the presence of a retroperitoneal tumor with displacement of the upper abdominal organs. Endoscopic retrograde cholangiopancreatography (ERCP) reveale that Wirsung's duct was displaced ventrad in a convex manner. The main pancreatic duct was slight narrowed in the prepapillary area with diminution of the small ducts. The common bile duct was stenosed, but the intrahepatic ducts and gallbladder were normal. The postmortem examination revealed the testicular teratoma and masses of confluent metastatic lymph nodes in the inguinal, paravertebral, para-aortic, mesenteric, and portal regions of the lymphatic system.

5927 EFFECT OF GLUCAGON INFUSION OF PLASMA CYCLIC AMP IN PATIENTS WITH CHOLESTATIC HEPATITIS AND OBSTRUCTIVE JAUNDICE. NEW TEST OF HEPATIC CHOLESTASIS. (Eng.) Francavilla, A.; Pansini, F.; Sansone, F.; Albano, O.; Martellotta, G. (Div. Gastroenterology, Univ. Bari, Bari, Italy *Clin. Chim. Acta* 75(3):351-357; 1977.

Plasma cyclic AMP levels during glucagon infusion (200 ng/kg/min, i.v., over 60 min) were determined in 10 patients with cholestatic hepatitis (hepatit A and B), 9 patients with extrahepatic obstructive jaundice, and 8 normal subjects. Plasma cyclic AM levels during glucagon infusion were greater in patients with jaundice or hepatitis than in normal subjects. In controls, cyclic AMP concentration rose promptly from a basal value of 15 ± 2 to a maximal value of 610 ± 73 pmol/ml at the 30th min of infusion, followed by a slight decrease to values of 441 ± 72 and 327 ± 65 pmol/ml at 50 and 60 min of infusion, resp. In patients with cholestatic hepatitis, cyclic AMP rose from a basa value of 32 ± 2 to a maximal value of 840 ± 125 pmol/ml at the 40th min and then decreased slightl to 725 ± 120 pmol/ml at the 60th min of infusion. Statistically significant differences from control were observed only at the 60th min ($p<0.02$). Cycl AMP levels in patients with obstructive jaundice rose rapidly from a basal value of 40 ± 2 pmol/ml to a maximal plateau value of 800 ± 70 pmol/ml at the 20th min of infusion. Almost all values observed over the 60-min infusion period for patients with obstructive jaundice differed significantly from those of controls. A statistically significant difference ($p<0.001$) in plasma cyclic AMP concentrations was found between patients with cholestatic hepatitis (164 ± 25 pmol/ml) and patients with obstructive jaundice (473 ± 50 pmol/ml) at the 10th min of glucagon infusion. These results indicate that plasma cyclic AMP levels at the 10th min of glucagon infusion represent a reliable diagnostic index of cholestatic jaundice. It is estimated that wherever cyclic AMP plasma concentration is 10 times higher than the basal value at the 10th min of glucagon infusion, obstructive jaundice is present.

5928 CHANGES IN ORGAN-SPECIFIC ENZYME ACTIVITY AND ULTRASTRUCTURE OF LIVER CELLS IN CHOLELITHIASIS. (Rus.) Blyuger, A. F.; Maiorg, A. Ya.; Mutsenieks, P. P.; Bolotova, M. A.; Kartashova, O. Ya.; Zaltsmane, V. K. (Riga Medical Inst., USSR). *Vopr. Med. Khim.* 23(4):435-440; 1977.

5929 BALLISTO-CARDIOGRAPHY IN HEPATOBILIARY SYSTEM LESIONS IN CHILDREN. (Ukr.) Zelenetsky, V. S. (Kiev Medical Inst., USSR). *Pediatr. Akush. Ginekol.* (3):6-7; 1977.

See also, 5265, 5514, 5515, 5517, 5520, 5524, 5525, 5535, 5542, 5546, 5551, 5554, 5632, 5774, 5793, 5800, 5804, 5825, 5837, 5845, 5950, 5955, 5956, 5963.

GENERAL

5930 ANAL PRESSURE STUDIES IN SPINAL PATIENTS. (Eng.) Wheatley, I. C.; Hardy, K. J.; Dent, J. (Repatriation General and Austin Hosp., Melbourne, Australia). *Gut* 18(6):488-490; 1977.

Maximal anal sphincter pressure was measured in 18 patients with spinal cord lesions and in a group of 10 controls, using a new technique, perfused sleeve manometry. With this system, the region of maximal pressure can move along the length of the sleeve without any significant change in the pressure registered. The mean resting pressure of the spinal patients was 63 ± 8 mm Hg, and of the control group 116 ± 14 mm Hg ($p<0.01$). When the rectum was distended by a balloon inflated with 100 ml of air, anal sphincter pressure fell to 33 ± 6 mm Hg in the spinal group and to 78 ± 10 mm Hg in the control group.

5931 BILE SALT METABOLISM IN CHRONIC UNSPECIFIC ENTEROPATHIES WITH BACTERIAL INVASION. (Ger.) Fodor, O.; Dumitrascu, D.; Grigorescu, M.; Serban, D.; Suciu, A. (Clinica III medicala, str. lasilor nr. 16, Cluj-Napoca, Rumania). *Dtsch. Z. Verdau. Stoffwechselkr.* 36(1):17-21; 1976.

The intraluminal metabolism of bile salts was studied in 30 patients with nonspecific enteropathies with bacterial invasion (13 patients with Reichel-Polya stomach resection, 11 with normochlorhydria, 6 with achlorhydria). The contents of the small intestine (obtained by stomach tube in the morning and 12 hr after the last meal) were studied in aero- and anaerobiotic media; bile salts were determined enzymatically with 3-alpha-hydroxysteroid dehydrogenase. The following bacteria were found in the jejunal juice: *Mima polymorpha* (10 cases), *Escherichia coli* (6), *Bacterium anitratum* (2), *Staphylococcus albus* (8), *S. aureus* (2), *Streptococcus fecalis* (7), and hemolytic streptococci (8). The concentration of conjugated bile acids (glyco- and tauro-conjugated) in the jejunum was significantly lower in patients with chronic enteropathies or invasion by bacteria that metabolize bile salts, while free bile acids remained constant. Conjugated bile acid levels returned to normal following oral treatment with wide spectrum antibiotics (mean 8.24 ± 1.32 μmol/ml), whereas free bile acids disappeared or dropped markedly in the contents of the small intestines. The relation between the bile acid fractions returned to normal at the same time; these changes paralleled a marked decrease in the number of bacteria or a sterilization of the intestinal contents. Intraluminal metabolism of bile salts, as known in blind-loop syndrome, also occurs in chronic nonspecific enteropathies with bacterial invasion.

5932 PHENFORMIN AND HYPERAMYLASEMIA IN LACTIC ACIDOSIS. (Eng.) Conlay, L. A.; Loewenstein, J. E. (Louisiana State Univ., Sch. Medicine, Shreveport, LA 71130). *Ann. Intern. Med.* 87(3):312-313; 1977.

Twenty-six cases of lactic acidosis (metabolic acidosis with arterial lactate >5.0 mM or an unexplained anion gap >20 mEq/1) occurring during a 23-month period in a metropolitan hospital were reviewed to ascertain the frequency of hyperamylasemia. Serum amylase activity had been measured in 12 of 26 patients and was elevated (>200 IU) in eight (67%). Hyperamylasemia was not significantly more frequent in patients with phenformin-associated lactic acidosis than in patients with lactic acidosis who had not received phenformin, suggesting that this drug is not responsible for increased amylase activity. Serum amylase activity did not correlate with the severity of acidosis (arterial pH) or with renal function (serum creatinine). Other possibilities such as macroamylasemia, laboratory artifact, or release of amylase from tissues other than the pancreas have yet to be investigated.

5933 INFLUENCE OF CARBON CHAIN LENGTH OF DIETARY FAT ON INTESTINAL ALKALINE PHOSPHATASE IN CHYLOUS ASCITES. (Eng.) Malagelada, J. R.; Stolbach, L. L.; Linscheer, W. G. (Tufts Univ. Sch. Medicine, Boston, MA). *Am. J. Dig. Dis.* 22(7):629-632; 1977.

To clarify the relation between lymphatic transport of intestinal alkaline phosphatase (IAP) and fat ingestion, two patients in whom leakage from the intestinal lymphatic system into the peritoneal cavity produced chylous ascites were studied. Both patients had lymphatic leakage that was due to obstruction. During baseline studies both patients were maintained on a standard diet containing 100 g long-chain triglycerides (LCT). A medium-chain triglyceride (MCT) diet containing 110 g MCT was substituted for the LCT diet for 13 and 8 days in each patient, resp. After the MCT diet, both patients resumed the previous LCT diet for at least another 2 weeks. Substitution of MCT for LCT produced a marked decrease of the triglyceride concentrations in chylous ascites, which subsequently became cleared. The decrease in triglyceride concentrations was associated with a decrease in total alkaline phosphatase activity in chylous ascites. The decrease was due to a selective fall in the IAP fraction. With the resumption of the LCT diet, IAP, total alkaline phosphatase activity, and triglyceride levels returned to baseline levels. IAP activity and triglyceride concentration in chylous ascites were linearly related in both patients, suggesting a positive relation between absorption of LCT and transport of mucosal alkaline phosphatase into lymph.

5934 EVALUATION OF A SUCROSE/ELECTROLYTE SOLUTION FOR ORAL REHYDRATION IN ACUTE INFANTILE DIARRHEA. (Eng.) Chatterjee, A.; Jalan, K. N.; Agarwal, S. K.; Mahalanabis, D.; Maitra, T. K.; Bagchi, D. K.; Indra, S. (Calcutta Medical Res. Inst., 7/2 Diamond Harbour Rd., Calcutta 27, India). *Lancet* 1(8026):1333-1335; 1977.

The efficacy of a sucrose-based p.o. electrolyte solution in the treatment of children (median age 1 yr) with severe to moderate dehydration caused by acute diarrhea was studied in 20 patients, and the effect of a temporary depression of sucrase in the small bowel mucosa during acute diarrhea was examined in 16 cases. A p.o. sucrose/electrolyte solution (in mM; 50, Na; 15, K; 50, Cl; 15, HCO_3; and sucrose, 130; 15 ml/kg/hr) brought about complete hydration in 19/20 children. The amount of fluid needed for initial hydration was 214.1 ± 13.8 ml/kg, and the time required to achieve this was 14.2 ± 0.94 hr. One child did not respond and required i.v. therapy. Vomiting, abdominal distention, and the appearance of sugar in the stools during p.o. hydration did not interfere with the success of the treatment. A satisfactory response was shown by weight gain (9.2 ± 0.6%), restoration of plasma bicarbonate to normal levels, decreases in the hematocrit values and in the plasma specific gravity, and complete clinical recovery. Disaccharidases in jejunal mucosal biopsy specimens in the acute phase showed reduced lactase in 75% and reduced sucrase in 18%; maltase levels were adequate. Except for the child who did not respond, all patients showed a satisfactory rise in blood sugar after sucrose and glucose tolerance tests. Since sucrose is cheaper and more easily obtained than glucose, its use in electrolyte solutions is indicated.

5935 CLINICAL FEATURES OF ACUTE GASTROENTERITIS ASSOCIATED WITH HUMAN REOVIRUS-LIKE AGENT IN INFANTS AND YOUNG CHILDREN. (Eng.) Rodriguez, W. J.; Kim, H. W.; Arrobio, J. O.; Brandt, C. D.; Chanock, R. M.; Kapikian, A. Z.; *et al.* (Children's Hosp. Natl. Medical Center, 111 Michigan Ave., N.W., Washington, DC 20010). *J. Pediatr.* 91(2): 188-193; 1977.

The clinical features of 72 infants and children with a human reovirus-like agent (HRVLA) are described. The cases were detected between January 1974 and June 1975 in 152 infants and children hospitalized with acute gastroenteritis. Seventy-six percent of infants and children 7-12 months of age and 76% of those 13-24 months of age had infection with the HRVLA, whereas such infection was found in only 21% of infants under 6 months of age and 23% of children 25-60 months of age. Sixty-one percent of patients studied during the cooler months had HRVLA infection, and such infection was no found from June to October. Twice as many HRVLA-infected patients had vomiting (92%) and significant dehydration (83%). It appears that certain epidemiological and clinical findings are helpful in distinguishing gastroenteritis due to HRVLA from other causes in hospitalized children: age, time of year, and frequency of vomiting and dehydration.

5936 PROTRACTED DIARRHOEA IN INFANCY: ANALYSIS OF 82 CASES WITH PARTICULAR REFERENCE TO DIAGNOSIS AND MANAGEMENT. (Eng.) Larcher, V. F.; Shepherd, R.; Francis, D. E. M.; Harries, J. T. (King's Coll. Hosp., Denmark Hill, SE5 8RX, England). *Arch. Dis. Child.* 52(8):597-605; 1977.

The diagnosis and management in 82 cases of protracted diarrhea in infancy presenting over a 6-yr period were analyzed. The patients fell into one of two categories according to whether a specific diagnosis was established. A diagnosis (category 1) was established in 59, the commonest diagnoses being celiac disease (33.2%), secondary disaccharide intolerance (12.2%), and cows' milk protein intolerance (11.3%). Other diagnoses included primary sucrase-isomaltase deficiency, Shwachman's syndrome, ulcerative colitis, ganglioneuroma, defective opsonization, staphylococcal pneumonia, and Hirschsprung's disease. Despite intensive investigation, a diagnosis could not be established in 23 infants (category 2). Age of onset of symptoms in this group tended to be earlier than in category 1 patients, and six presented with diarrhea dating from birth. There was a high incidence of associated extraintestinal anomalies in these six patients, and in siblings who had died after protracted diarrhea dating from birth. Four of the six infants died, accounting for a mortality of 5% for the whole series. The remaining 17 patients in category 2 presented at a mean age of 4.9 weeks with a range of 1-18 weeks. All these 17 patients made an excellent response after institution of a chicken-based dietary formula. The pathophysiological mechanisms that may be operating in infants with protracted diarrhea are discussed. The authors speculate that, in a proportion of affected patients, an acute infective insult renders the small intestine susceptible to intolerance of foreign proteins and/or bacterial colonization, and that this sequence of events may be important in the pathogenesis of the diarrhea and malnutrition.

5937 A CRITIQUE OF ORAL THERAPY OF DEHYDRATION DUE TO DIARRHEAL SYNDROMES. (Eng.)

Nichols, B. L.; Soriano, H. A. (Baylor Coll. Medicine, Houston, TX 77030). *Am. J. Clin. Nutr.* 30(9):1457-1472; 1977.

Approaches to the management of diarrheal syndrome that have the potential for wide application in developing countries are reviewed. Under the circumstances of limited health resources and immediate need for preventing the dehydration associated with diarrhea in infants, breast-feeding should be encouraged throughout the diarrheal episode. When this is not possible because of cessation or failure of lactation, a p.o. electrolyte solution should be administered. It should be sterile and provide a quantity of electrolytes not greatly in excess of 30 mEq/l of sodium and potassium. There should be little possibility of an error in the dilution of the mixture if it is to be supplied in powdered form. Milk should be reintroduced after 24 hr and the electrolyte mix rapidly discontinued so as to minimize nutritional deficits. If no such electrolyte mixture is available, it is reasonable to alternate feedings of commercial soft drinks or bland teas with milk feedings. There should be specific instructions that the infant should be brought to the hydration center if more than three sequential feedings are lost by vomiting, if fever is present, or if the stools exceed the volume of three feedings. In general, dehydration of less than 5% of body weight can be managed by this program in the home. Dehydration greater than 5% but less than 10% requires supervision by health authorities. Dehydration greater than 10% requires i.v. therapy in a hydration center. In those countries with cholera and during epidemics of shigellosis or enterotoxigenic *Escherichia coli*, solutions containing 90 mEq/l of sodium should be given under ambulatory supervision. This solution should be discontinued when fecal losses moderate (<60 ml/kg/day) and the lower electrolyte solution (30 mEq/l) substituted.

5938 MORPHOLOGICAL AND FUNCTIONAL CHANGES OF THE SMALL INTESTINAL MUCOSA IN PATIENTS WITH KIDNEY DISEASES OF VARIOUS DEGREES OF INSUFFICIENCY, AND IN PATIENTS RECEIVING HEMODIALYSIS. PART 1: MORPHOLOGICAL CHANGES OF THE SMALL INTESTINAL MUCOSA. (Ger.)

Sperschneider, H.; Stein, G.; Kuhne-Heid, R.; Kunath, H. (Medizinische Klinik des Bereiches Medizin, Friedrich-Schiller-Universitat, Bachstr. 18, DDR-69 Jena, E. Germany). *Dtsch. Gesundheitsw.* 31(51):2408-2412; 1976.

Morphological changes of the small intestinal mucosa were studied in 115 hospitalized patients with chronic pyelonephritis (61 patients) and glomerulonephritis (54) of various degrees of renal insufficiency. Twenty-six of the patients had chronic intermittent hemodialysis for less than 6 months up to 4 yr. Microscopic and histologic examination of small intestinal biopsy material from 77 patients showed a significant increase in pathological findings, with deterioration of renal function as evidenced by villous fusion and atrophy as well as marked inflammatory changes of the mucous membrane. Pathological readings in lactose tolerance, iron absorption, and fat absorption tests were associated with progressive renal insufficiency. Disturbances in lactose absorption were also seen in intact small intestinal mucosa. The disturbances in fat and lactose absorption were significantly reduced by long-term hemodialysis treatment, whereas no change in decreased iron absorption was noted. Thus, the histological changes (enteritis, villous fusion, and atrophy) are reversible (partly due to hemodialysis), but the authors also note the importance of diet in epithelial regeneration, since malnutrition is imminent in progressive renal insufficiency until dialysis is instituted.

5939 THE SIGNIFICANCE OF STARCH POWDER CONTAMINATION IN THE AETIOLOGY OF PERITONEAL ADHESIONS. (Eng.)

Cooke, S. A. R.; Hamilton, D. G. (Dept. Surgery, Univ. Witwatersrand, Johannesburg, South Africa). *Br. J. Surg.* 64(6):410-412; 1977.

The frequency, clinical features, and natural history of peritoneal starch granuloma and adhesion formation from starch glove powder were studied in 20 patients who each underwent two laparotomies within a 1-month to 9-yr period. Starch granulomas or adhesions containing starch were found at the second laparotomy in 10 patients. Among the 20 patients, starch granulomas were present within adhesions at the second operation in 6 of the 15 patients with adhesions and within adhesions in 2 of the 4 patients presenting with intestinal band obstruction. In the 10 patients with starch granulomas within peritoneal nodules or adhesions, the time interval between the first and second operation was less than 24 months, and in 7 of the 10 patients, this interval was less than 12 months. Those adhesions containing starch granulomas and occurring in patients whose initial laparotomy had occurred more than 3 months previously appeared to have a mature structure. In those patients showing no evidence of starch granulomas, only two underwent the second laparotomy within 24 months of the first. The original pathology or the procedure performed at the first laparotomy included colon perforation or colon resection (5 patients with starch granuloma, 4 without), small bowel perforation (3 with, 1 without), laparotomy and colostomy (3 with, 1 without), perforated peptic ulcer (0 with, 2 without), and total esophagectomy (1 with, 0 without). The evidence suggests that granuloma formation is common in the early months following operation and that adhesions associated with starch granulomas cause intestinal obstruction. Although starch is usually absorbed within 2 yr, associated band adhesions may persist. Glove powder contamination of the peritoneal cavity may be a common cause of band adhesion obstruction.

5940 THE REMOVAL OF GASTRIN-SECRETING TISSUE IN THE TREATMENT OF ZOLLINGER-ELLISON SYNDROME. (Fre.) Joyeux, R.; Colin, R.; Nicot, H.; Combettes, P. S. (Clinique Chirurgicale A, Montpellier, Cliniques Saint Eloi, 2, rue Bertin-Sans, 34059 Montpellier Cedex, France). *J. Chir. (Paris)* 113(5/6):457-470; 1977.

A review of the literature revealed 24 cases of Zollinger-Ellison syndrome that were treated by the removal of the gastrin-secreting tumor rather than by a total gastrectomy. The removal of the entire gastrinoma is easily verified by the preoperative measurement of serum gastrin levels, which should drop within 30 min of the removal of gastrin secreting tissues. Of the 24 patients, 12 had malignant tumors, and 11 of them showed no further neoplastic evolution after 4 months to 9 years. Peptic ulcers healed spontaneously in 13/14 patients. In contrast, of 78 other patients with Zollinger-Ellison syndrome treated by total gastrectomy, only 16 survived more than 3 yr. A total gastrectomy must still be considered if the gastrinoma cannot be found or removed or if there is a recurrence of the ulcers or neoplasm.

5941 DIAGNOSTIC SIGNIFICANCE OF THE SECRETIN PROVOCATION TEST IN ZOLLINGER-ELLISON SYNDROME. ANALYSIS OF 21 CONSECUTIVE POSITIVE SECRETIN TESTS. (Fre.) Mignon, M.; Accary, J. P.; Bonfils, S. (INSERM U-10, Hopital Bichat, 170, boulevard Ney, F-75877 Paris Cedex 18, France). *Gastroenterol. Clin. Biol.* 1(5):425-434; 1977.

Secretin provocation tests were administered to 20 patients; 12 with confirmed and 8 with suspected Zollinger-Ellison syndrome. Secretin (3 U/kg, i.v.) was infused during a 60-min period after 60 min of basal observation. Serum gastrin levels and acid secretion were measured every 15 min. There was a significant increase in serum gastrin in 9/12 confirmed Zollinger-Ellison cases and in 6/8 suspected cases. Acid secretion was significantly increased in five of nine patients, but the results did not pa allel gastrin increases in four cases. It is conclu that the secretin provocation test may be a valuable diagnostic aid, although the results are not as informative in patients who have recurrent ulcers after a partial gastrectomy as in patients who have undergone no prior surgery.

5956 PERFORATION OF HYDATID CYST INTO THE COMMON BILE DUCT: REPORT OF FOUR CASES. (Eng.) Man, B.; Kraus, L.; Motovic, A. (Meir Hosp., Tel Aviv, Israel). *Trop. Geogr. Med.* 29(1):95-98; 1977.

Four cases of hydatid cysts that perforated into the common bile duct are presented. The patients ranged in age from 22 to 39 yr. Jaundice was present in three cases, and fever, vomiting, and right upper abdominal pain were other presenting symptoms. Eosinophilia was present in three cases, and other laboratory findings were consistent with obstructive jaundice. The surgical treatment consisted of choledochotomy, evacuation of the daughter cysts in the common bile duct and of the echinococcosis mother cyst, and drainage through a T-tube. In one case, it was possible to open the mother cyst, evacuate its contents, and drain it externally. Perforation of a hydatid cyst into the common bile duct is an important complication, as it may present as an unsuspected cause of obstructive jaundice.

5957 NEMATODE LARVAE (SPIRURIDA [sic]: Physalopteridae) CAUSING INFARCTION OF THE BOWEL IN AN INFANT. (Eng.) Nicolaides, N. J.; Musgrave, J.; McGuckin, D.; Moorhouse, D. E. (Wickham Terrace, Brisbane, Australia). *Pathology* 9(2):129-135; 1977.

The case is reported of an 11-month-old boy with gangrene of the distal small bowel due to infestation by larval worms belonging to the order Spirurida, family Physalopteridae, and probably the genus *Physaloptera*. The initial symptoms included vomiting and a fleeting cutaneous rash. Microscopically, the resected bowel showed ischemic necrosis, eosinophilic granulomata, and larval worms in the lumen and wall of blood vessels. The inflammatory process extended into the mesentery, where the vessels showed focal necroses, thrombosis, and endarteritis. Infection in this child in the Queensland countryside is considered to have resulted from ingestion of insects on grass eaten when at play, the grass having been contaminated by bandicoots.

Regional Enteritis

5977 EVIDENCE FOR A TRANSMISSIBLE FACTOR IN CROHN'S DISEASE. (Eng.) Donnelly, B. J.; Delaney, P. V.; Healy, T. M. (Dept. Surgery, Univ. Coll., Dublin, Ireland). *Gut* 18(5):360-363; 1977.

To investigate the possibility that a transmissible factor exists in Crohn's disease, rabbit ileum was injected with normal and Crohn's-affected human bowel homogenates, and the effects of adding ampicillin to the homogenates were investigated. Crohn's-like changes were present 6 months after the injection of normal human bowel in 7 of 11 rabbits and after the injection of human Crohn's tissue in 4 of 16 rabbits; 12 months after the injection, the rabbit bowel had reverted to normal. The addition of ampicillin (125,000 U/ml) to the homogenates prevented the appearance of these Crohn's-like changes in all of six animals injected with normal human bowel and in all of six animals injected with Crohn's tissue. These results suggest that a transmissible factor present in both normal and Crohn's-affected bowel is involved in the etiology of Crohn's disease.

5978 TREATMENT OF RECTOCOLONIC CROHN'S DISEASE BY IMMUNODEPRESSIVE DRUGS. (Fre.) Delmont, J.; Vedel, J. P.; Faure, X.; Rampal, P. (Hopital du Cimiez, 4, av. Reine-Victoria, 06000 Nice, France). *Ann. Gastroenterol. Hepatol.* 13(4): 347-355; 1977.

A series of 19 patients with confirmed Crohn's disease were treated by a combination of azathioprine and cortisone for 6 months and were evaluated at 1 month, 6 months, and 1, 2, and 3 yr. Cortisone was given as 40 mg the first half month, 30 mg the second half month, 20 mg the second month, 15 mg the third month, and 10 mg for 3 months following. Azathioprine was given as three tablets for 1 month and 2 tablets for the 5 subsequent months. All the patients showed a good improvement 1 month after the treatment started, and 17/19 were still improved after 6 months. After 2 yr, only 6/14 patients were still well without any further treatment, 6/14 patients remained symptomless on a maintenance dose of the drugs, 2/14 needed surgical treatment, and 1 patient died; reports for 4 patients were unavailable. At 3 yr, seven patients on a maintenance dose showed good results, and three patients not continuing treatment showed good results; results were unavailable for seven patients. These results seem to indicate that the value of azathioprine may lie in its ability to lower the effective dose of jointly administered cortisone.

5979 ENZYMATIC AND MORPHOMETRIC EVIDENCE FOR CROHN'S DISEASE AS A DIFFUSE LESION OF THE GASTROINTESTINAL TRACT. (Eng.) Dunne, W. T.; Cooke, W. T.; Allan, R. N. (Dept. Biological Science, Univ. Aston in Birmingham, Birmingham, England). *Gut* 18(4):290-294; 1977.

Studies were carried out in patients with distal Crohn's disease to determine whether changes in jejunal mucosal enzymes in these patients support the concept of Crohn's disease as a diffuse lesion of the gastrointestinal tract. Intestinal disaccharidase and dipeptidase activities were measured in mucosal biopsies from the proximal jejunum in 20 patients with Crohn's disease apparently confined to the distal ileum or large bowel, 14 control patients with ulcerative colitis, and 14 healthy controls. The dissecting microscopy and histological appearance of all of the biopsies were normal (grades 0-1), except for those of two patients with Crohn's disease and one patient with ulcerative colitis, which showed grade 2 changes. Biopsy morphometry showed a reduction of jejunal mucosal surface area and an increase in mucosal volume in patients with Crohn's disease when compared with the other two groups. The mucosal enzymes studies demonstrated that patients with Crohn's disease had a significant reduction in brush border enzymes (disaccharidase), but no change in cytoplasmic enzyme activity (dipeptidases). All three disaccharidases (lactase, trehalase, and sucrase) were significantly reduced in the patients with Crohn's disease, compared with the other two groups. The enzyme levels in patients with ulcerative colitis did not differ from the healthy controls. The reduction of brush border enzymes with normal cytoplasmic enzymes in the presence of abnormal morphometry is further evidence of the concept of Crohn's disease as a diffuse lesion of the gastrointestinal tract. It also suggests that there is either specific damage to the microvilli or some other abnormality such as impairment of enzyme synthesis in Crohn's disease.

5980 CROHN'S DISEASE OF THE DUODENUM. (Eng.) Nugent, F. W.; Richmond, M.; Park, S. K. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Gut* 18(2):115-120; 1977.

A review of 36 patients with Crohn's disease involving the duodenum is presented. Crohn's disease elsewhere in the gastrointestinal tract was seen in 32 of these patients. Upper abdominal pain and symptoms of gastroduodenal obstruction were the commonest symptoms of presentation. Significant weight loss was common, and occasionally major upper gastrointestinal bleeding occurred. The commonest radiologic pattern of involvement (20 patients) was contiguous involvement of the gastric antrum and proximal duodenum. The earliest radiologic features were irregular thickening, edema, and a cobblestone pattern of the mucosa. As the disease progressed, stenosis became a prominent finding. Eventually, stenosis became severe, and a string sign developed. Endoscopically, diffuse granularity, nodularity, and ulceration were seen accompanied by a lack of distensibility of the involved area.

Twelve patients had all of the histological features of Crohn's disease, including granulomas. However, granulomas were not demonstrated in any of 17 patients who had endoscopic biopsies, and only one of three capsule biopsies performed demonstrated granulomas. Operative bypass was carried out in 18 patients, with gastroenterostomy and vagotomy being performed in six patients, gastroenterostomy in six patients, Billroth II procedure and vagotomy in three patients, Billroth II procedure in two patients, and duodenojejunostomy in one patient. After an average follow-up of 6.6 yr (range, 1-19 yr), 15 of these patients are free of all significant upper gastrointestinal symptoms. When symptoms of obstruction dictate, operative bypass is accompanied by favorable long-term results in the large majority of patients.

5981 PROBLEMS RELATED TO A PATIENT WITH CROHN'S DISEASE COMPLICATED BY ANAL FISTULA AND TWO BIPOLAR EPIDERMOID CARCINOMAS OF THE ANAL MARGIN. (Fre.) Pradel, E.; Rodier, B. (Hopital St.-Joseph, 7, rue Pierre-Larousse, 75014 Paris, France). *Ann. Gastroenterol. Hepatol.* 13(4):307-310; 1977.

The case of a 36-yr-old man with ileocecal Crohn's disease who developed an anal fistula after 11 yr and two successive epidermoid carcinomas of the anal margin 16 yr after hemicolectomy is reported. For 6 yr, he had been receiving continuous low doses of corticosteroids for spondylarthritis. The fistula was routinely corrected. The first carcinoma was treated by cobalt therapy, 8,270 rads to the anal area and 3,630 rads to each of the two oblique posterior areas. Five months later, another anal epidermoid carcinoma, without perceptible adenopathy, was discovered; it was widely extirpated. Immunologic studies showed a normal cellular immunity and a lowered lymphocyte reactivity. The patient was strongly hypersensitive to pneumoallergens and was negative for anticolon antibodies. Since the patient showed no further sign of cancer, it was decided not to resort to any chemotherapy or immunotherapy for the present. This is the first reported case of epidermoid carcinoma complicating Crohn's disease.

5982 MICROGRANULOMAS IN GROSSLY NORMAL RECTAL MUCOSA IN CROHN'S DISEASE. (Eng.) Rotterdam, H.; Korelitz, B. I.; Sommers, S. C. (Lenox Hill Hosp., 100 East 77th St., New York, NY 10021). *Am. J. Clin. Pathol.* 67(6):550-554; 1977.

Rectal biopsies of sigmoidoscopically normal mucosa from 99 patients with Crohn's disease of the ileum, colon, or both were studied histologically, with particular reference to the presence of granulomas. A total of 23 granulomas were found in six patients with Crohn's disease of the colon, four with ileocolitis, and four with ileitis. Eleven granulomas were of the usual sarcoid type and were easily detected under low-power microscopy. They varied in diameter from 250-660 μm, with an average of 500 μm. Twelve microgranulomas were of loose composition and were recognized only under high power microscopic examination. They ranged in diameter from 125-200 μm, with an average of 180 μm. All patients who had granulomas had clinically active disease, while most patients with microgranulomas had clinically inactive disease. Five granulomas were located in the middle third of the mucosa, four in the lower third near the muscularis, and two in the submucosa. Eight microgranulomas were located in the upper third of the mucosa near the surface, two in the middle third, and two in the lower third. The finding of microgranulomas in patients with both colonic and ileal involvement in Crohn's disease indicates the need to examine carefully every serial section and emphasizes that not every granuloma in Crohn's disease has the typical mature, sarcoid-like appearance. The superficial mucosal location of the majority of microgranulomas indicates that colonic microgranulomas do not arise in lymphatic walls.

5983 RECTAL BIOPSY IN PATIENTS WITH CROHN'S DISEASE: NORMAL MUCOSA ON SIGMOIDOSCOPIC EXAMINATION. (Eng.) Korelitz, B. I.; Sommers, S. C. (Lenox Hill Hosp., 100 E. 77th St., New York, NY 10021). *JAMA* 237(25):2742-2744; 1977.

The question of whether histologic abnormalities are common enough in the sigmoidoscopically normal rectal mucosa of patients with ileal or colonic Crohn's disease to justify a routine rectal biopsy in these patients was investigated. Of 99 patients whose rectal segment was endoscopically normal, there was histologic inflammation in 45% and features characteristic of Crohn's disease in 30% of rectal biopsy specimens. Granulomas occurred in 18% of the patients, including 13% of those with ileitis, 13% of those with ileocolitis, and 37% of those with colitis. Eleven of the 17 granulomas were small, undemarcated microgranulomas. Rectal biopsy specimens are valuable in the confirmation of the diagnosis of Crohn's disease and in the determination of the state of clinical activity even when the sigmoidoscopic appearance is normal.

5984 ISOLATED HUMAN INTESTINAL MUCOSAL LYMPHOID CELLS: ALTERATIONS IN INFLAMMATORY BOWEL DISEASE (IBD) [Abstract]. (Eng.) Bookman, M. A.; Helms, R. A.; Bull, D. M. (Harvard Medical Sch. at Beth Israel Hosp., Boston, MA). *Gastroenterology* 72 (5, Part 2):1155; 1977.

5985 CROHN'S DISEASE INVOLVING THE ESOPHAGUS AND COLON: CASE REPORT. (Eng.) Miller, L. J.; Thistle, J. L.; Payne, W. S.; Gaffey, T. A.; O'Duffy, J. D. (Mayo Graduate Sch. Medicine, Rochester, MN). *Mayo Clin. Proc.* 52(1):35-38; 1977.

5986 ADENOCARCINOMA OF THE SMALL INTESTINE IN CROHN DISEASE INVOLVING THE SMALL BOWEL. (Eng.) Burbige, E. J.; Bedine, M. S.; Handelsman, J. C. (Veterans Admin. Hosp., 150

Muir Rd., Martinez, CA 94553). *West. J. Med.* 127(1):43-45; 1977.

5987 COMPLEMENT ACTIVITY IN INFLAMMATORY DISEASES OF THE COLON. (Fre.) Giroux, Y.; Boileau, J.; Mignon, M. F. (Hopital Maisonneuve-Rosemont, Montreal, Canada). *Union Med. Can.* 105 (11):1681-1685; 1977.
